Aristotle indicates several times in VII.11-14 that merely to say that pleasure is *a* good does not do it enough justice; he also wants to say that the highest good is a pleasure. Here he is influenced by an idea expressed in the opening line of the *Ethics*: the good is that at which all things aim. In VII.13, he hints at the idea that all living things imitate the contemplative activity of god (1153b31-2). Plants and non-human animals seek to reproduce themselves because that is their way of participating in an unending series, and this is the closest they can come to the ceaseless thinking of the unmoved mover. Aristotle makes this point in several of his works (see for example *De Anima* 415a23-b7), and in *Ethics* X.7-8 he gives a full defense of the idea that the happiest human life resembles the life of a divine being. He conceives of god as a being who continually enjoy a "single and simple pleasure" (1154b26) -- the pleasure of pure thought -- whereas human beings, because of their complexity, grow weary of whatever they do. He will elaborate on these points in X.8; in VII.11-14, he appeals to his conception of divine activity only in order to defend the thesis that our highest good consists in a certain kind of pleasure. Human happiness does not consist in every kind of pleasure, but it does consist in one kind of pleasure -- the pleasure felt by a human being who engages in theoretical activity and thereby imitates the pleasurable thinking of god.

Book X offers a much more elaborate account of what pleasure is and what it is not. It is not a process, because processes go through developmental stages: building a temple is a process because the temple is not present all at once, but only comes into being through stages that unfold over time. By contrast, pleasure, like seeing and many other activities, is not something that comes into existence through a developmental process. If I am enjoying a conversation, for example, I do not need to wait until it is finished in order to feel pleased; I take pleasure in the activity all along the way. The defining nature of pleasure is that it is an activity that accompanies other activities, and in some sense brings them to completion. Pleasure occurs when something within us, having been brought into good condition, is activated in relation to an external object that is also in good condition. The pleasure of drawing, for example, requires both the development of drawing ability and an object of attention that is worth drawing.

The conception of pleasure that Aristotle develops in Book X is obviously closely related to the analysis he gives in Book VII. But the theory proposed in the later Book brings out a point that had received too little attention earlier: pleasure is by its nature something that accompanies something else. It is not enough to say that it is what happens when we are in good condition and are active in unimpeded circumstances; one must add to that point the further idea that pleasure plays a certain role in

complementing something other than itself. Drawing well and the pleasure of drawing well always occur together, and so they are easy to confuse, but Aristotle's analysis in Book X emphasizes the importance of making this distinction.

He says that pleasure completes the activity that it accompanies, but then adds, mysteriously, that it completes the activity in the manner of an end that is added on. In the translation of W.D. Ross, it "supervenes as the bloom of youth does on those in the flower of their age" (1174b33). It is unclear what thought is being expressed here, but perhaps Aristotle is merely trying to avoid a possible misunderstanding: when he says that pleasure completes an activity, he does not mean that the activity it accompanies is in some way defective, and that the pleasure improves the activity by removing this defect. Aristotle's language is open to that misinterpretation because the verb that is translated "complete" (*teleein*) can also mean "perfect." The latter might be taken to mean that the activity accompanied by pleasure has not yet reached a sufficiently high level of excellence, and that the role of pleasure is to bring it to the point of perfection. Aristotle does not deny that when we take pleasure in an activity we get better at it, but when he says that pleasure completes an activity by supervening on it, like the bloom that accompanies those who have achieved the highest point of physical beauty, his point is that the activity complemented by pleasure is already perfect, and the pleasure that accompanies it is a bonus that serves no further purpose. Taking pleasure in an activity does help us improve at it, but enjoyment does not cease when perfection is achieved -- on the contrary, that is when pleasure is at its peak. That is when it reveals most fully what it is: an added bonus that crowns our achievement.

It is clear, at any rate, that in Book X Aristotle gives a fuller account of what pleasure is than he had in Book VII. We should take note of a further difference between these two discussions: In Book X, he makes the point that pleasure is *a* good but not *the* good. He cites and endorses an argument given by Plato in the *Philebus*: If we imagine a life filled with pleasure and then mentally add wisdom to it, the result is made more desirable. But the good is something that cannot be improved upon in this way. Therefore pleasure is not the good (1172b23-35). By contrast, in Book VII Aristotle strongly implies that the pleasure of contemplation *is* the good, because in one way or another all living beings aim at this sort of pleasure. Aristotle observes in Book X that what all things aim at is good (1172b35-1173a1); significantly, he falls short of endorsing the argument that since all aim at pleasure, it must be *the* good.

Book VII makes the point that pleasures interfere with each other, and so even if all kinds of pleasures are good, it does not follow that all of them are worth choosing. One must make a selection among pleasures by determining which are better. But how is one to make this choice? Book VII does not say, but in Book X, Aristotle holds that the selection of pleasures is not to be made with reference to pleasure itself, but with reference to the activities they accompany. "Since activities differ with respect to goodness and badness, some being worth choosing, others worth avoiding, and others neither, the same is true of pleasures as well" (1175b24-6). Aristotle's statement implies that in order to determine whether (for example) the pleasure of virtuous activity is more desirable than that of eating, we are not to attend to the pleasures themselves but to the activities with which we are pleased. A pleasure's goodness derives from the goodness of its associated activity. And surely the reason why pleasure is not the criterion to which we should look in making these decisions is that it is not the good. The standard we should use in making comparisons between rival options is virtuous activity, because that has been shown to be identical to

happiness.

That is why Aristotle says that what is judged pleasant by a good man really is pleasant, because the good man is the measure of things (1176a15-19). He does not mean that the way to lead our lives is to search for a good man and continually rely on him to tell us what is pleasurable. Rather, his point is that there is no way of telling what is genuinely pleasurable (and therefore what is most pleasurable) unless we already have some other standard of value. Aristotle's discussion of pleasure thus helps confirm his initial hypothesis that to live our lives well we must focus on one sort of good above all others: virtuous activity. It is the good in terms of which all other goods must be understood. Aristotle's analysis of friendship supports the same conclusion.

9. Friendship

The topic of Books VIII and IX of the *Ethics* is friendship. Although it is difficult to avoid the term "friendship" as a translation of "*philia*," and this is an accurate term for the kind of relationship he is most interested in, we should bear in mind that he is discussing a wider range of phenomena than this translation might lead us to expect, for the Greeks use the term, "*philia*," to name the relationship that holds among family members, and do not reserve it for voluntary relationships. Although Aristotle is interested in classifying the different forms that friendship takes, his main theme in Books VIII and IX is to show the close relationship between virtuous activity and friendship. He is vindicating his conception of happiness as virtuous activity by showing how satisfying are the relationships that a virtuous person can normally expect to have.

His taxonomy begins with the premise that there are three main reasons why one person might like someone else. (The verb, "*philein*," which is cognate to the noun "*philia*," can sometimes be translated "like" or even "love" -- though in other cases *philia* involves very little in the way of feeling.) One might like someone because he is good, or because he is useful, or because he is pleasant. And so there are three bases for friendships, depending on which of these qualities binds friends together. When two individuals recognize that the other person is someone of good character, and they spend time with each other, engaged in activities that exercise their virtues, then they form one kind of friendship. If they are equally virtuous, their friendship is perfect. If, however, there is a large gap in their moral development (as between a parent and a small child, or between a husband and a wife), then although their relationship may be based on the other person's good character, it will be imperfect precisely because of their inequality.

The imperfect friendships that Aristotle focuses on, however, are not unequal relationships based on good character. Rather, they are relationships held together because each individual regards the other as the source of some advantage to himself or some pleasure he receives. When Aristotle calls these relationships "imperfect," he is tacitly relying on widely accepted assumptions about what makes a relationship satisfying. These friendships are defective, and have a smaller claim to be called "friendships," because the individuals involved have little trust in each other, quarrel frequently, and are ready to break off their association abruptly. Aristotle does not mean to suggest that unequal relations

based on the mutual recognition of good character are defective in these same ways. Rather, when he says that unequal relationships based on character are imperfect, his point is that people are friends in the fullest sense when they gladly spend their days together in shared activities, and this close and constant interaction is less available to those who are not equal in their moral development.

When Aristotle begins his discussion of friendship, he introduces a notion that is central to his understanding of this phenomenon: a genuine friend is someone who loves or likes another person for the sake of that other person. Wanting what is good for the sake of another he calls "good will" (*eunoia*), and friendship is reciprocal good will, provided that each recognizes the presence of this attitude in the other. Does such good will exist in all three kinds of friendship, or is it confined to relationships based on virtue? At first, Aristotle leaves open the first of these two possibilities. He says: "it is necessary that friends bear good will to each other and wish good things for each other, without this escaping their notice, because of one of the reasons mentioned" (1156a4-5). The reasons mentioned are goodness, pleasure, and advantage; and so it seems that Aristotle is leaving room for the idea that in all three kinds of friendships, even those based on advantage and pleasure alone, the individuals wish each other well for the sake of the other.

But in fact, as Aristotle continues to develop his taxonomy, he does not choose to exploit this possibility. He speaks as though it is only in friendships based on character that one finds a desire to benefit the other person for the sake of the other person. "Those who wish good things to their friends for the sake of the latter are friends most of all, because they do so because of their friends themselves, and not coincidentally" (1156b9-11). When one benefits someone not because of the kind of person he is, but only because of the advantages to oneself, then, Aristotle says, one is not a friend towards the other person, but only towards the profit that comes one's way (1157a15-16).

In such statements as these, Aristotle comes rather close to saying that relationships based on profit or pleasure should not be called friendships at all. But he decides to stay close to common parlance and to use the term "friend" loosely. Friendships based on character are the ones in which each person benefits the other for the sake of other; and these are friendships most of all. Because each party benefits the other, it is advantageous to form such friendships. And since each enjoys the trust and companionship of the other, there is considerable pleasure in these relationships as well. Because these perfect friendships produce advantages and pleasures for each of the parties, there is some basis for going along with common usage and calling any relationship entered into for the sake of just one of these goods a friendship. Friendships based on advantage alone or pleasure alone deserve to be called friendships because in full-fledged friendships these two properties, advantage and pleasure, are present. It is striking that in the *Ethics* Aristotle never thinks of saying that the uniting factor in all friendships is the desire each friend has for the good of the other.

Aristotle does not raise questions about what it is to desire good for the sake of another person. He treats this as an easily understood phenomenon, and has no doubts about its existence. But it is also clear that he takes this motive to be compatible with a love of one's own good and a desire for one's own happiness. Someone who has practical wisdom will recognize that he needs friends and other resources in order to exercise his virtues over a long period of time. When he makes friends, and benefits friends he has made,

he will be aware of the fact that such a relationship is good for him. And yet to have a friend is to want to benefit someone for that other person's sake; it is not a merely self-interested strategy. Aristotle sees no difficulty here, and rightly so. For there is no reason why acts of friendship should not be undertaken partly for the good of one's friend and partly for one's own good. Acting for the sake of another does not in itself demand self-sacrifice. It requires caring about someone other than oneself, but does not demand some loss of care for oneself. For when we know how to benefit a friend for his sake, we exercise the ethical virtues, and this is precisely what our happiness consists in.

Aristotle makes it clear that the number of people with whom one can sustain the kind of relationship he calls a perfect friendship is quite small (IX.10). Even if one lived in a city populated entirely by perfectly virtuous citizens, the number with whom one could carry on a friendship of the perfect type would be at most a handful. For he thinks that this kind of friendship can exist only when one spends a great deal of time with the other person, participating in joint activities and engaging in mutually beneficial behavior; and one cannot cooperate on these close terms with every member of the political community. One may well ask why this kind of close friendship is necessary for happiness. If one lived in a community filled with good people, and cooperated on an occasional basis with each of them, in a spirit of good will and admiration, would that not provide sufficient scope for virtuous activity and a well-lived life? Admittedly, close friends are often in a better position to benefit each other than are fellow citizens, who generally have little knowledge of one's individual circumstances. But this only shows that it is advantageous to be on the receiving end of a friend's help. The more important question for Aristotle is why one needs to be on the giving end of this relationship. And obviously the answer cannot be that one needs to give in order to receive; that would turn active love for one's friend into a mere means to the benefits received.

Aristotle attempts to answer this question in IX.11, but his treatment is disappointing. His fullest argument depends crucially on the notion that a friend is "another self," someone, in other words, with whom one has a relationship very similar to the relationship one has with oneself. A virtuous person loves the recognition of himself as virtuous; to have a close friend is to possess yet another person, besides oneself, whose virtue one can recognize at extremely close quarters; and so, it must be desirable to have someone very much like oneself whose virtuous activity one can perceive. The argument is unconvincing because it does not explain why the perception of virtuous activity in fellow citizens would not be an adequate substitute for the perception of virtue in one's friends.

Aristotle would be on stronger grounds if he could show that in the absence of close friends one would be severely restricted in the kinds of virtuous activities one could undertake. But he cannot present such an argument, because he does not believe it. He says that it is "finer and more godlike" to bring about the well being of a whole city than to sustain the happiness of just one person (1094b7-10). He refuses to regard private life -- the realm of the household and the small circle of one's friends -- as the best or most favorable location for the exercise of virtue. He is convinced that the loss of this private sphere would greatly detract from a well-lived life, but he is hard put to explain why. He might have done better to focus on the benefits of being the object of a close friend's solicitude. Just as property is ill cared for when it owned by all, and just as a child would be poorly nurtured were he to receive no special parental care -- points Aristotle makes in *Politics* II.2-5 -- so in the absence of friendship we would lose a benefit that could not be replaced by the care of the larger community. But Aristotle is not looking for a defense of

this sort, because he conceives of friendship as lying primarily in activity rather than receptivity. It is difficult, within his framework, to show that virtuous activity towards a friend is a uniquely important good.

Since Aristotle thinks that the pursuit of one's own happiness, properly understood, requires ethically virtuous activity and will therefore be of great value not only to one's friends but to the larger political community as well, he argues that self-love is an entirely proper emotion -- provided it is expressed in the love of virtue (IX.8). Self-love is rightly condemned when it consists in the pursuit of as large a share of external goods -- particularly wealth and power -- as one can acquire, because such self-love inevitably brings one into conflict with others and undermines the stability of the political community. It may be tempting to cast Aristotle's defense of self-love into modern terms by calling him an egoist, and "egoism" is a broad enough term so that, properly defined, it can be made to fit Aristotle's ethical outlook. If egoism is the thesis that one will always act rightly if one consults one's self-interest, properly understood, then nothing would be amiss in identifying him as an egoist.

But egoism is sometimes understood in a stronger sense. Just as consequentialism is the thesis that one should maximize the general good, whatever the good turns out to be, so egoism can be defined as the parallel thesis that one should maximize one's own good, whatever the good turns out to be. Egoism, in other words, can be treated as a purely formal thesis: it holds that whether the good is pleasure, or virtue, or the satisfaction of desires, one should not attempt to maximize the total amount of good in the world, but only one's own. When egoism takes this abstract form, it is an expression of the idea that the claims of others are never worth attending to, unless in some way or other their good can be shown to serve one's own. The only underived reason for action is self-interest; that an act helps another does not by itself provide a reason for performing it, unless some connection can be made between the good of that other and one's own.

There is no reason to attribute this extreme form of egoism to Aristotle. On the contrary, his defense of self-love makes it clear that he is not willing to defend the bare idea that one ought to love oneself alone or above others; he defends self-love only when this emotion is tied to the correct theory of where one's good lies, for it is only in this way that he can show that self-love need not be a destructive passion. He takes it for granted that self-love is properly condemned whenever it can be shown to be harmful to the community. It is praiseworthy only if it can be shown that a self-lover will be an admirable citizen. In making this assumption, Aristotle reveals that he thinks that the claims of other members of the community to proper treatment are intrinsically valid. This is precisely what a strong form of egoism cannot accept.

We should also keep in mind Aristotle's statement in the *Politics* that the political community is prior to the individual citizen -- just as the whole body is prior to any of its parts (1253a18-29). Aristotle makes use of this claim when he proposes that in the ideal community each child should receive the same education, and that the responsibility for providing such an education should be taken out of the hands of private individuals and made a matter of common concern (1337a21-7). No citizen, he says, belongs to himself; all belong to the city (1337a28-9). What he means is that when it comes to such matters as education, which affect the good of all, each individual should be guided by the collective decisions of the

whole community. An individual citizen does not belong to himself, in the sense that it is not up to him alone to determine how he should act; he should subordinate his individual decision-making powers to those of the whole. The strong form of egoism we have been discussing cannot accept Aristotle's doctrine of the priority of the city to the individual. It tells the individual that the good of others has, in itself, no valid claim on him, but that he should serve other members of the community only to the extent that he can connect their interests to his own. Such a doctrine leaves no room for the thought that the individual citizen does not belong to himself but to the whole.

10. Three Lives Compared

In Book I Aristotle says that three kinds of lives are thought to be especially attractive: one is devoted to pleasure, a second to politics, and a third to knowledge and understanding (1095b17-19). In X.6-9 Aristotle returns to these three alternatives, and explores them more fully than he had in Book I. The life of pleasure is construed in Book I as a life devoted to physical pleasure, and is quickly dismissed because of its vulgarity. In X.6, Aristotle concedes that physical pleasures, and more generally, amusements of all sorts, are desirable in themselves, and therefore have some claim to be our ultimate end. But his discussion of happiness in Book X does not start from scratch; he builds on his thesis that pleasure cannot be our ultimate target, because what counts as pleasant must be judged by some standard other than pleasure itself, namely the judgment of the virtuous person. Amusements will not be absent from a happy life, since everyone needs relaxation, and amusements fill this need. But they play a subordinate role, because we seek relaxation in order to return to more important activities.

Aristotle turns therefore, in X.7-8, to the two remaining alternatives -- politics and philosophy -- and presents a series of arguments to show that the philosophical life, a life devoted to *theoria* (contemplation, study), is best. *Theoria* is not the process of learning that leads to understanding; that process is not a candidate for our ultimate end, because it is undertaken for the sake of a further goal. What Aristotle has in mind when he talks about *theoria* is the activity of someone who has already achieved theoretical wisdom. The happiest life is lived by someone who has a full understanding of the basic causal principles that govern the operation of the universe, and who has the resources needed for living a life devoted to the exercise of that understanding. Evidently Aristotle believes that his own life and that of his philosophical friends was the best available to a human being. He compares it to the life of a god: god thinks without interruption and endlessly, and a philosopher enjoys something similar for a limited period of time.

It may seem odd that after devoting so much attention to the practical virtues, Aristotle should conclude his treatise with the thesis that the best activity of the best life is not ethical. In fact, some scholars have held that X.7-8 are deeply at odds with the rest of the *Ethics*; they take Aristotle to be saying that we should be prepared to act unethically, if need be, in order to devote ourselves as much as possible to contemplation. But it is difficult to believe that he intends to reverse himself so abruptly, and there are many indications that he intends the arguments of X.7-8 to be continuous with the themes he emphasizes throughout the rest of the *Ethics*. The best way to understand him is to take him to be assuming that one will need the ethical virtues in order to live the life of a philosopher, even though exercising those virtues is not the philosopher's ultimate end. To be adequately equipped to live a life of thought and discussion,

one will need practical wisdom, temperance, justice, and the other ethical virtues. To say that there is something better even than ethical activity, and that ethical activity promotes this higher goal, is entirely compatible with everything else that we find in the *Ethics*.

Although Aristotle's principal goal in X.7-8 is to show the superiority of philosophy to politics, he does not deny that a political life is happy. Perfect happiness, he says, consists in contemplation; but he indicates that the life devoted to practical thought and ethical virtue is happy in a secondary way. He thinks of this second-best life as that of a political leader, because he assumes that the person who most fully exercises such qualities as justice and greatness of soul is the man who has the large resources needed to promote the common good of the city. The political life has a major defect, despite the fact that it consists in fully exercising the ethical virtues, because it is a life devoid of philosophical understanding and activity. Were someone to combine both careers, practicing politics at certain times and engaged in philosophical discussion at other times (as Plato's philosopher-kings do), he would lead a life better than that of Aristotle's politician, but worse than that of Aristotle's philosopher.

But his complaint about the political life is not simply that it is devoid of philosophical activity. The points he makes against it reveal drawbacks inherent in ethical and political activity. Perhaps the most telling of these defects is that the life of the political leader is in a certain sense unleisurely (1177b4-15). What Aristotle has in mind when he makes this complaint is that ethical activities are remedial: they are needed when something has gone wrong, or threatens to do so. Courage, for example, is exercised in war, and war remedies an evil; it is not something we should not wish for. Aristotle implies that all other political activities have the same feature, although perhaps to a smaller degree. Corrective justice would provide him with further evidence for his thesis -- but what of justice in the distribution of goods? Perhaps Aristotle would reply that in existing political communities a virtuous person must accommodate himself to the least bad method of distribution, because, human nature being what it is, a certain amount of injustice must be tolerated. As the courageous person cannot be completely satisfied with his courageous action, no matter how much self-mastery it shows, because he is a peace-lover and not a killer, so the just person living in the real world must experience some degree of dissatisfaction with his attempts to give each person his due. The pleasures of exercising the ethical virtues are, in normal circumstances, mixed with pain. Unalloyed pleasure is available to us only when we remove ourselves from the all-too-human world and contemplate the rational order of the cosmos. No human life can consist solely in these pure pleasures; and in certain circumstances one may owe it to one's community to forego a philosophical life and devote oneself to the good of the city. But the paradigms of human happiness are those people who are lucky enough to devote much of their time to the study of a world more orderly than the human world we inhabit.

Although Aristotle argues for the superiority of the philosophical life in X.7-8, he says in X.9, the final chapter of the *Ethics*, that his project is not yet complete, because we can make human beings virtuous, or good even to some small degree, only if we undertake a study of the art of legislation. The final section of the *Ethics* is therefore intended as an prolegomenon to Aristotle's political writings. We must investigate the kinds of political systems exhibited by existing Greek cities, the forces that destroy or preserve cities, and the best sort of political order. Although the study of virtue Aristotle has just completed is meant to be helpful to all human beings who have been brought up well -- even those who have no intention of

pursuing a political career -- it is also designed to serve a larger purpose. Human beings cannot achieve happiness, or even something that approximates happiness, unless they live in communities that foster good habits and provide the basic equipment of a well-lived life.

The study of the human good has therefore led to two conclusions: The best life is not to be found in the practice of politics. But the well being of whole communities depends on the willingness of some to lead a second-best life -- a life devoted to the study and practice of the art of politics, and to the expression of those qualities of thought and passion that exhibit our rational self-mastery.

Supplement to Aristotle's Ethics

Alternate Readings of Aristotle on *Akrasia*

That, at any rate, is one way of interpreting Aristotle's statements. But it must be admitted that his remarks are obscure and leave room for alternative readings. It is possible that when he denies that the akratic has knowledge in the strict sense, he is simply insisting on the point that no one should be classified as having practical knowledge unless he actually acts in accordance with it. A practical knower is not someone who merely has knowledge of general premises; he must also have knowledge of particulars, and he must actually draw the conclusion of the syllogism. Perhaps drawing such a conclusion consists in nothing less than performing the action called for by the major and minor premises. Since this is something the akratic does not do, he lacks knowledge; his ignorance is constituted by his error in action. On this reading, there is no basis for attributing to Aristotle the thesis that the kind of *akrasia* he calls weakness is caused by a diminution of intellectual acuity. His explanation of *akrasia* is simply that *pathos* is sometimes a stronger motivational force than full-fledged reason.

This is a difficult reading to defend, however, for Aristotle says that after someone experiences a bout of *akrasia* his ignorance is dissolved and he becomes a knower again (1147b6-7). In context, that appears to be a remark about the form of *akrasia* Aristotle calls weakness rather than impetuosity. If so, he is saying that when an akratic person is subject to two conflicting influences -- full-fledged reason versus the minimal rationality of emotion -- his state of knowledge is somehow temporarily undone but is later restored. Here, knowledge cannot be constituted by the performance of an act, because that is not the sort of thing that can be restored at a later time. What can be restored is one's full recognition or affirmation of the fact that this act has a certain undesirable feature, or that it should not be performed. Aristotle's analysis seems to be that both forms of *akrasia* -- weakness and impetuosity -- share a common structure: in each case, one's full affirmation or grasp of what one should do comes too late. The difference is that in the case of weakness but not impetuosity, the akratic act is preceded by a full-fledged rational cognition of what one should do right now. That recognition is briefly and temporarily diminished by the onset of a less than fully rational affect.

There is one other way in which Aristotle's treatment of *akrasia* is close to the Socratic thesis that what people call *akrasia* is really ignorance. Aristotle holds that if one is in the special mental condition that he calls practical wisdom, then one cannot be, nor will one ever become, an akratic person (1152a6-7). For practical wisdom is present only in those who also possess the ethical virtues, and these qualities require complete emotional mastery. Anger and appetite are fully in harmony with reason, if one is practically wise, and so this intellectual virtue is incompatible with the sort of inner conflict experienced by the akratic person. Furthermore, one is called practically wise not merely on the basis of what one believes or knows, but also on the basis of what one does. Therefore, the sort of knowledge that is lost

and regained during a bout of *akrasia* cannot be called practical wisdom. It is knowledge only in a loose sense. The ordinary person's low-level grasp of what to do is precisely the sort of thing that can lose its acuity and motivating power, because it was never much of an intellectual accomplishment to begin with. That is what Aristotle is getting at when he compares it with the utterances of actors, students, sleepers, drunks, and madmen.

Saint Augustine

Aurelius Augustinus [more commonly "St. Augustine of Hippo," often simply "Augustine"] (354-430 C.E.): *rhetor*, Christian Neoplatonist, North African Bishop, Doctor of the Roman Catholic Church. One of the decisive developments in the western philosophical tradition was the eventually widespread merging of the Greek philosophical tradition and the Judeo-Christian religious and scriptural traditions. Augustine is one of the main figures through and by whom this merging was accomplished. He is, as well, one of the towering figures of medieval philosophy whose authority and thought came to exert a pervasive and enduring influence well into the modern period (e.g. Descartes and especially Malebranche), and even up to the present day, especially among those sympathetic to the religious tradition which he helped to shape (e.g. Plantinga 1992; Adams 1999). But even for those who do not share this sympathy, there is much in Augustine's thought that is worthy of serious philosophical attention. Augustine is not only one of the major sources whereby classical philosophy in general and Neoplatonism in particular enter into the mainstream of early and subsequent medieval philosophy, but there are significant contributions of his own that emerge from his modification of that Greco-Roman inheritance, e.g., his subtle accounts of belief and authority, his account of knowledge and illumination, his emphasis upon the importance and centrality of the will, and his focus upon a new way of conceptualizing the phenomena of human history, just to cite a few of the more conspicuous examples.

Context

Only four of his seventy-five years were spent outside Northern Africa, and fifty-seven of the remaining seventy-one were in such relatively out of the way places as Thagaste and Hippo Regius, both belonging to Roman provinces, neither notable for either cultural or commercial prominence. However, the few years Augustine spent away from Northern Africa exerted an incalculable influence upon his thought, and his geographical distance from the major intellectual and political capitals of the Later Roman Empire should not obscure the tremendous influence he came to exert even in his own lifetime. Here, as elsewhere, one is confronted by a figure both strikingly liminal and, at times, intriguingly ambivalent. He was, as already noted, a long time resident and, eventually, Bishop in Northern Africa whose thought was transformed and redirected during the four brief years he spent in Rome and Milan, far away from the provincial context where he was born and died and spent almost all of the years in between; he was a man who tells us that he never thought of himself as not being in some sense a Christian [*Confessions* III.iv.8], yet he composed a spiritual autobiography containing one of the most celebrated conversion accounts in all of Christian literature; he was a classically trained rhetorician who used his skills to eloquently proclaim at length the superiority of Christian culture over Greco-Roman culture, and he also served as one of the central figures by whom the latter was transformed and transmitted to the former. Perhaps most striking of all, Augustine bequeathed to the Latin West a voluminous body of work that contains at its chronological extremes two quite dissimilar portraits of the human condition. In the beginning, there is a largely Hellenistic portrait, one that is notable for the optimism that a sufficiently rational and disciplined life can safely escape the ever-threatening circumstantial adversity that seems to surround us. Nearer the end, however, there emerges a considerably grimmer portrait, one that emphasizes the impotence of the unaided human will, and the later Augustine presents a moral landscape populated largely by the *massa damnata* [*De Civitate Dei* XXI.12], the overwhelming majority who are justly predestined to eternal punishment by an omnipotent God, intermingled with a small minority whom God, with unmerited mercy, has predestined to be saved. The sheer quantity of the writing that unites these two extremes, much of which survives, is truly staggering. There are well over 100 titles [listed at Fitzgerald 1999, pp. xxxv-il], many of which are themselves voluminous and composed over lengthy periods of time, not to mention over 200 letters [listed at Fitzgerald 1999, pp. 299-305] and close to 400 sermons [listed at Fitzgerald 1999, pp. 774-789]. It is arguably impossible to construct any moderate sized and manageable list of his major philosophical works that would not occasion some controversy in terms of what is omitted, but surely any list would have to include *Contra Academicos* [*Against the Academicians*, 386-387 C.E.], *De Libero Arbitrio* [*On Free Choice of the Will*, Book I, 387/9 C.E.; Books II & III, circa 391-395 C.E.], *De Magistro* [*On The Teacher*, 389 C.E.], *Confessiones* [*Confessions*, 397-401 C.E.], *De Trinitate* [*On The Trinity*, 399-422 C.E.], *De Genesi ad Litteram* [*On The Literal Meaning of Genesis*, 401-415 C.E.], *De Civitate Dei* [*On The City of God*, 413-427C.E.], and *Retractationes* [*Reconsiderations*, 426-427 C.E.].

Born in 354 C.E. in Thagaste (in what is now Algeria), he was educated in Thagaste, Madauros, and Carthage, and sometime around 370 he began a sixteen-year, monogamous relationship with the mother of his son, Adeodatus (born 372). He subsequently taught rhetoric in Thagaste and Carthage, and in 383 he made the risk-laden journey from Northern Africa to Rome, seeking the better sort of students that was rumored to be there. Disappointed by the moral quality of those students (academically superior to his previous students, they nonetheless had an annoying tendency to disappear without paying their fees), he successfully applied for a professorship of rhetoric in Milan. Augustine's professional ambitions pointed in the direction of an arranged marriage, and this in turn entailed a separation from his long-time

companion and mother of his son. After this separation, however, Augustine abruptly resigned his professorship in 386 claiming ill health, renounced his professional ambitions, and was baptized by Bishop Ambrose of Milan on Easter Sunday, 387, after spending four months at Cassiciacum where he composed his earliest extant works. Shortly thereafter, Augustine began his return to Northern Africa, but not before his mother died at Ostia, a seaport outside Rome, while awaiting the voyage across the Mediterranean. Not too long after this, Augustine, now back in Thagaste, also lost his son (389). The remainder of his years would be spent immersed in the affairs and controversies of the Church into which he had been recently baptized, a Church that henceforth provided for Augustine the crucial nexus of relations that his family and friends had once been. In 391, Augustine was reluctantly ordained as a priest by the congregation of Hippo Regius (a not uncommon practice in Northern Africa), in 395 he was made Bishop, and he died August 430 in Hippo, thirty-five years later, as the Vandals were besieging the gates of the city. However, when Augustine himself recounts his first thirty-two years in his *Confessions*, he makes clear that many of the decisive events of his early life were, to use his own imagery, of a considerably more internal nature than the relatively external facts cited above.

From his own account, he was a precocious and able student, much enamored of the Latin classics, Virgil in particular [*Confessions* I.xiii.20]. However, at age nineteen, he happened upon Cicero's *Hortensius*, now lost except for fragments [see Straume-Zimmermann 1990], and he found himself suddenly imbued with a passion for philosophy [*Confessions* III.iv.7-8]. It is clear from his account of Cicero's effect upon him that his passion was not for philosophy as often understood today, i.e. an academic, largely argument-oriented conceptual discipline, but rather as the paradigmatically Hellenistic pursuit of a wisdom that transcended and blurred the boundaries of what are now viewed as the separate spheres of philosophy, religion, and psychology. In particular, philosophy for Augustine was centered on what is sometimes misleadingly referred to as "the problem of evil." This problem, needless to say, was not the sort of analytic, largely logical problem of theodicy that later came to preoccupy philosophers of religion. For Augustine, the problem was of a more general and visceral sort: it was the concern with the issue of how to make sense of and live within a world that seemed so adversarial and fraught with danger, a world in which so much of what matters most to us is so easily lost [see e.g. *Confessions* IV.x.15]. In this sense, the wisdom that Augustine sought was a common denominator uniting the conflicting views of such Hellenistic philosophical sects as the Epicureans, Stoics, Skeptics, and Neoplatonists (though this is a later title) such as Plotinus and Porphyry, as well as many Christians of varying degrees of orthodoxy, including very unorthodox gnostic sects such as the Manicheans.

Augustine himself comes to spend nine years as a hearer among the Manicheans [see Brown 1967, pp. 46-60], and while there are no extant writings from this period of his life, the Manicheans are clearly the target of many of the writings he would compose after his conversion to the more orthodox, if Neoplatonizing, Christianity he encountered under Bishop Ambrose of Milan. The Manicheans proposed a powerful, if somewhat mythical and philosophically awkward explanation of the problem of evil: there is a perpetual struggle between co-eternal principles of Light and Darkness (good and evil, respectively), and our souls are particles of Light which have become trapped in the Darkness of the physical world. By means of sufficient insight and a sufficiently ascetic life, however, one could eventually, over the course of several lives, come to liberate the Light within from the surrounding Darkness, thus rejoining the larger Light of which the soul is but a fragmented and isolated part.

As Augustine recounts it in the *Confessions* [see *Confessions* V.3.5 and V.7.13] and elsewhere [e.g. *De Moribus Ecclesiae Catholicae* 1], he became disenchanted with the inability of the Manichean elect to provide sufficiently detailed and rigorous explanations of their cosmology. As a result, he began to drift away from the sect during his sojourn in Rome, flirting for awhile with academic skepticism [*Confessions* V.xiv.25] before finally coming upon the Platonizing influence of Ambrose and the "books of the Platonists" [*Confessions* VII.9.13]. When Augustine eventually comes to write about the Manicheans, there are three features upon which he will focus: their implicit materialism (a widespread feature of Hellenistic thought, the Neoplatonists being a notable exception); their substantive dualism whereby Darkness, and hence, evil, is granted a co-eternal, substantial existence opposed to the Light; and their identification of the human soul as a fragmented particle of the Light. According to Augustine, this latter identification not only serves to render the human soul divine, thereby obliterating the crucial distinction between creator and creature, but it also raises doubts about the extent to which the individual human soul can be held responsible for morally bad actions, responsibility instead being attributed to the body in which the soul (itself quasi material) is trapped. Although Augustine is vehement and at times merciless in his repudiation of the Manicheans, questions can still be asked about the influence the Manichean world-view continued to exert upon his understanding and presentation of Neoplatonic and Christian themes [see "Philosophical Anthropology" below].

The single most decisive event, however, in Augustine's philosophical development has to be his encounter with those unnamed books of the Platonists in Milan in 384. While there are other important influences, it was his encounter with the Platonism ambient in Ambrose's Milan that provided the major turning point, reorienting his thought along basic themes that would persist until his death forty-six years later. There has been controversy regarding just which books of the Platonists Augustine encountered [O'Connell 1968, pp. 6-10; O'Donnell 1992, vol. II, pp. 421-423; Beatrice, 1989], but we know from his own account that they were translated by Marius Victorinus [*Confessions* VIII.2.3], and there is widespread agreement that they were texts by Plotinus and Porphyry, although there is again controversy regarding how much influence is to be attributed to each [O'Connell 1968, pp. 20-26; O'Donnell 1992, vol II, pp. 423-4]. These uncertainties notwithstanding, Augustine himself makes it clear that it was his encounter with the the books of the Platonists that made it possible for him to view both the Church and its scriptural tradition as having an intellectually satisfying and, indeed, resourceful content.

As decisive as this encounter was, however, it would be a mistake simply to view Augustine's writings as the uncritical application of a Neoplatonic framework to a static body of Christian doctrine. In his earliest writings [e.g. *Contra Academicos*, 386 C.E.], Augustine is amazingly confident with regard to the compatibility of the two traditions [see *Contra Academicos* 3.10.43]. But by the time he composes the *Confessions* (397-401C.E.), he is already aware that there are significant points of divergence [*Confessions* VII.20.26], and by the time he composes Book VIII of *De Civitate Dei* (circa 416 C.E.), he still has laudatory things to say about the Platonic tradition, but it is clear that the points of divergence have become more important to him and that he regards the Roman Catholic Church as having sufficient internal resources to address whatever difficulties confront it. Part of this gradual change of attitude is attributable to his detailed study of scriptural texts (especially the Pauline letters), as well as his immersion in both the daily affairs of his monastic community and the rather focused sorts of controversies that confronted the Church in the fourth and fifth centuries. Beyond his already noted,

protracted battle with Manicheanism, there is also his involvement in the North African Donatist controversy [see Brown 1967, pp. 212-225], a controversy concerning the validity of sacraments administered in the wake of the persecution of 304-305, and most especially the Pelagian controversy which engaged him from about 411 until his death in 430 [see Brown 1967, pp. 340-52 and the section on "Will" below]. In this latter case, serious issues arose regarding the role of grace and the efficacy of the unaided human will, issues that, as we will see, played an important role in shaping his views on human freedom and predestination.

These important qualifications notwithstanding, the fact remains that this Platonism also provided Augustine with a philosophical framework far more pliable and enduring than he himself is willing to admit in his later works. Moreover, this framework itself forms an important part of the philosophical legacy that Augustine bequeathed to both the medieval and modern periods.

Perhaps a good place to begin an examination of this legacy is to begin with that upon which Augustine himself focuses when he recounts the impact that the books of the Platonists had upon him, i.e. his ontology, and the eudaimonism it is intended to support.

Ontology and Eudaimonism

In the *Confessions*, where Augustine gives his most extensive discussion of the impact of the books of the Platonists, he makes clear that he regards his previous thinking as having been dominated by a common-sense materialism [*Confessons* IV.xv.24; VII.i.1]. It was the books of the Platonists that first made it possible for him to conceive the possibility of a non-physical substance [*Confessions* VII.x.16], providing him with a non-Manichean solution to the problem of the origin of evil. In addition, the books of the Platonists provided him with a metaphysical framework of extraordinary depth and subtlety, a richly textured tableau upon which the human condition can be plotted. It can both account for the obvious difficulties with which life confronts us, while presenting them them within a much larger context that provides grounds for a eudaimonism notable for the depth of its moral optimism. In this respect, the ontology that Augustine acquired from the books of the Platonists is, in terms of its intent, not all that different from the materialism of the Epicureans, Stoics, and even the Manicheans. What sets the Neoplatonic ontology apart, however, is both the resoluteness of its promise and the architectonic grandeur with which it complements the world of visible appearances.

In the books of the Platonists, Augustine encountered an ontology in which there is a fundamental divide between the sensible/physical and the intelligible/spiritual [*Confessions* VII.x.16]. In spite of the dualistic implications, this is clearly not intended to be a dualistic alternative to the moral dualism of the Manicheans and other gnostics [see, e.g. Plotinus, *Enneads* II.9]. Instead, the divide is situated within what is supposed to be a larger, unified hierarchy that begins with absolute unity and progressively unfolds through various stages of increasing plurality and multiplicity, culminating in the lowest realm of isolated and fragmented material objects observed with the senses [see Bussanich 1996, pp. 38-65; O'Meara 1996, pp. 66-81]. Thus, for Augustine, God is regarded as the ultimate source and point of origin for all that comes below. Equated with Being [*Confessions* VII.x.16], Goodness [e.g. *De Trinitate* VIII.5],

and Truth [*Confessions* X.xxiii.33; *De Libero Arbitrio* III.16], God is the unchanging point which unifies all that comes after and below within an abiding and providentially ordained rational hierarchy.

Augustine, especially in his earlier works, focuses upon the contrast between the intelligible and the sensible, enjoining his reader to realize that the former alone holds out what we seek in the latter: the world of the senses is intractably private and isolated, whereas the intelligible realm is truly public and simultaneously open to all [*De Libero Arbitrio* II.7] ; the sensible world is one of transitory objects, whereas the intelligible realm contains abiding realities [*De Libero Arbitrio* II.6]; the sensible world is subject to the consumptive effects of temporality, whereas the intelligible realm is characterized by an atemporal eternity wherein we are safely removed from the eviscerating prospect of losing what and whom we love [*Confessions* XI.xxxix.39; see also *Confessions* IV.xii.18]. Indeed, in the vision at Ostia at *Confessions* IX.x.23-25, Augustine even seems to suggest that the intelligible realm holds out the prospect of fulfilling our desire for the unity that we seek in friendship and love, a unity that can never really be achieved as long as we are immersed in the sensible world and separated by physical bodies subject to inevitable dissolution [see Mendelson 2000]. The intelligible realm, with God as its source, promises the only lasting relief from the anxiety prompted by the transitory nature of the sensible realm.

Despite its dualistic overtones, the overall unity of the picture is central to its ability to provide a resolution of the problem of evil. The sensible world, for example, is not evil, nor is embodiment itself to be regarded as straightforwardly bad. The problem that plagues our condition is not that we are trapped in the visible world (as it is for the Manicheans); rather, it is a more subtle problem of perception and will: we are prone to view things materialistically and hence unaware that the sensible world is but a tiny portion of what is real [*Confessions* IV.xv.24], an error Augustine increasingly attributes to original sin [*De Libero Arbitrio* III.20; *De Civitate Dei* XIII.14-15]. Thus, we have a tendency to focus only upon the sensible, viewing it as a self-contained arena within which all questions of moral concern are to be resolved. Because we fail to perceive the larger unity of which the sensible world is itself a part, it easily becomes for us (though not in itself) a realm of moral danger, one wherein our will attaches itself to transitory objects that cannot but lead to anxiety [*Confessions* VII.xi.17-18]. Given the essentially rational nature of the human soul and the rational nature of the Neoplatonic ontology, there is nonetheless room for optimism. The human soul has the capacity to perceive its own liminal status as a being embodied partly in the sensible world while connected to the intelligible realm, and there is thus the possibility of reorienting one's moral relation to the sensible world, appreciating it for the goodness it manifests, but seeing it as an instrument for directing one's attention to what is above it [see *Confessions* VII.x.16 and VII.xvii.23]. Augustine's employment of this Neoplatonic hierarchy is thus central to his Hellenistic eudaimonism [see O'Connell 1972, pp. 39-40; Rist 1994, pp. 48-53; Kirwan 1999, pp. 183-4] which would redeem appearances by means of situating them within a more primary, if often unacknowledged context.

With respect to questions about specific instances of natural and moral evil, this ontology is even more subtle. Natural evils are attributed to the partiality of our perspective, a perspective that is often the result of our myopic materialism and tendency to focus upon our own self-interest. Understood within the larger context -- both the underlying order of the appearances and the providentially governed moral drama within which they appear -- natural evils are not evil at all [e.g. *Confessions* VII.xiii.19 and *De Civitate*

Dei XI.22]. With respect to the moral evil which is the product of human agency, these are the culpable products of a will that has become attached to lower goods, treating them as if they were higher. Moral evil is, strictly speaking, not a thing, but only the will's turning away from God and attaching itself to inferior goods as if they were higher [ibid.]. In *De Civitate Dei*, Augustine emphasizes the privative nature of evil by referring to the will's pursuit of inferior goods as being a deficient rather than efficient cause [*De Civitate Dei*, XII.7]. The inherent difficulty of this notion aside [see Rist 1994, pp. 106-8], the point behind it is clear enough: Augustine is using the resources of Neoplatonism to account for the phenomena we label evil while stressing human responsibility, thus avoiding either substantializing evil (as the Manicheans do) or making it the result of God's creative activity.

For all that Augustine takes from the books of the Platonists, there are two points where he conspicuously departs from their ontology. Frequently, Plotinus asserts that the ultimate principle, The One, is itself of such absolute unity and transcendence that, strictly speaking, it defies all predication and is itself beyond Being and Goodness [see, for example, Plotinus, *Enneads*, VI.9.3]. Augustine himself does not comment upon this feature of Plotinus' thought, and thus one can only conjecture as to his reason for resisting it, but given his repeated emphasis upon the soul's relation to God [e.g. *Soliloquia* 1.2.7 and *De Ordine* 2.18.47], the Plotinian picture may have seemed to him as positing too great a distance between the two, thus raising doubts about the ability of reason to take us towards our desired destination [see Mendelson 1995, pp. 244-45]. The other departure from Neoplatonism moves in the opposite direction. Rather than the danger of making the spiritual distance between God and the soul too great, there is as well in Neoplatonism a tendency to bridge that gap in a manner troubling to someone like Augustine, for whom the creator/creature distinction is fundamental. In Plotinus and other Neoplatonists, the relation of the ultimate principle to all that comes below is usually presented in terms of a sempiternal process of necessary emanations whereby lower stages constantly flow from the higher [see Plotinus, *Enneads IV.8.6*]. Augustine, not surprisingly, resists this aspect of the Neoplatonic ontology, always insisting upon the fundamentally volitional nature of God's activity [e.g. *De Genesi ad Litteram* 6.15.26]. Nor should it be surprising that Augustine should find himself obliged to depart in important respects from the Neoplatonic tradition. He is, after all, not merely taking over a Neoplatonic ontology, but he is attempting to combine it with a scriptural tradition of a rather different sort, one wherein the divine attributes most prized in the Greek tradition (e.g. necessity, immutability, and atemporal eternity) must somehow be combined with the personal attributes (e.g. will, justice, and historical purpose) of the God of Abraham, Isaac, and Jacob.

For all the changes that affected Augustine between his initial encounter with the books of the Platonists in 384-386 and his death in 430, he never abandoned this Neoplatonic ontology's distinction between the physical/sensible and the spiritual/intelligible and its hierarchy within which these realms are unified. However, these commitments still leave much room for development as well as for tension and uncertainty. In particular, Augustine's views on original sin and the necessity of grace in the face of the Pelagian controversy raised serious questions about the efficacy of the human will. Complicating the matter further is the question of the soul's origin, a question that has a significant impact on Augustine's philosophical anthropology.

Philosophical Anthropology

With respect to Augustine's desire to find a viable alternative to the awkward and intractable moral dualism of the Manicheans, there can be little question that his embracing of Neoplatonism is a positive development. Not only does it allow him to account for evil without substantializing it, but it also provides him with a unified account of the moral drama that constitutes the human condition. Even so, this metaphysical architectonic is prone to tensions of its own, some of which lend themselves to a kind of moral dualism not altogether unlike that of the Manicheans.

For Augustine, the individual human being is a body-soul composite, but in keeping with his Neoplatonism, there is an asymmetry between soul and body. As a spiritual entity, the soul is superior to the body, and it is the province of the soul to rule the body [e.g. *De Animae Quantitate* 13.22; *De Genesi contra Manicheos* II.11]. This presents a fairly positive conception of the soul-body relation, one that clearly runs counter to the Manichean picture of the soul's entrapment. Matters are somewhat less clear, however, when we turn to the question of how the soul comes to be embodied.

With respect to the soul's "origin," as Augustine frames the question, there is a strand of uncertainty that runs unbroken from his earliest completed post-conversion work [*De Beata Vita*, 386 C.E.] to the *Retractationes* of 427 C.E. In both works, Augustine professes to be puzzled about the soul's origin [*De Beata Vita* 1.5 and *Rectractationes* 1.1 and 2.45/71], but his uncertainty is clearly evolving, and the absence of certainty on the issue should not be interpreted as neutrality or indifference.

It is also important to note that, for Augustine, this evolving uncertainty is itself to be understood against the backdrop of other points about which he never seems to waver after 386. He became adamant, for example, that the soul is to be identified with neither the substance of God, nor with the body, nor with any other material entity [*Letters 143* and *166*.3-4]. In addition to the status of the soul as both created and immaterial (both points contrasting with the Manicheans), he also insists upon the mutability of the human soul, a feature that not only serves to distinguish it from its creator but one that he views as necessary to explain the possibility of moral change, be it for better or worse [*Letter 166*.3; *Confessions* IV.xv.26].

In *De Libero Arbitrio* III.20 & 21 (circa 395 C.E.), when Augustine first attends to the question of the soul's origin in a manner that focuses upon particular possibilities, he does so as part of an anti-Manichean theodicy intended to show that it is the human soul rather than God that is responsible for the presence of moral evil in the world. Thus, as he later points out in *Letter 143* (circa 412 C.E.), he is not concerned to adjudicate between these competing hypotheses, but merely to show that each is consistent with a non-Manichean, Neoplatonizing account of moral evil. Nonetheless, the four hypotheses he does advance are important evidence about how he understands the conceptual landscape [O'Daly 1987, pp. 15-20; Mendelson 1998, pp. 30-44], and the anti-Manichean polemic notwithstanding, it is instructive that he makes no attempt to choose between or even to offer a tentative ranking of them.

Interestingly enough, two of the four hypotheses require the soul's existence prior to embodiment. On the

first, the soul is sent by God to administer the body (henceforth the "sent" hypothesis); on the second, the soul comes to inhabit the body by its own choice (henceforth the "voluntarist" hypothesis). In later presentations of these hypotheses (though not in *De Libero Arbitrio* III), Augustine treats the voluntarist hypothesis as involving both a sin on the soul's part and a cyclical process whereby the soul is subject to multiple incarnations [*Letter 166*.27]. The other two hypotheses, the "traducianist" and the "creationist," do not involve pre-existence, but there is nonetheless a significant contrast between them. On the traducianist account, all souls are propagated from Adam's soul in a manner analogous to that of the body, thus linking each soul to all previous ones by a kind of genealogical chain. On the creationist hypothesis, however, God creates a new soul for each body, thus creating a kind of vertical link between God and each individual soul.

These hypotheses do not exhaust the logical possibilities, but they were the main contenders in Augustine's time. There remains controversy over the extent to which Augustine himself was inclined towards either of the hypotheses that required pre-existence [O'Connell 1968, O'Daly 1987, pp. 15-20; O'Donnell 1992 II.34-5], but there are passages in the *Confessions* [see *Confessions* I.6-8] and elsewhere [e.g. *De Genesi Contra Manicheos* 2.8 (circa 388-9 C.E.) and *De Genesi ad Literam Imperfectus Liber* 1.3 (circa 393 C.E.)] that have led some to regard it as a possibility he takes very seriously indeed, perhaps even preferring it, at least until the early part of the fifth century [O'Connell 1968; Teske 1991]. Moreover, given the Neoplatonic architectonic of the *Confessions*, this would not be all that surprising, for the notion that the preexistent soul falls into the body is a conspicuous feature of Plotinus' thought as well as of Neoplatonism in general [e.g. Plotnius, *Enneads* IV.8; Origen, *On First Principles* 1.4.4]. In this regard, it is also not surprising that Augustine should have come to identify the hypothesis of the soul's voluntary descent into the body as involving both sin and cyclicism. Not only are these features reminiscent of what he eventually came to learn of Origen's view, but given the Neoplatonic framework underlying his conception of the soul's origin, it is difficult to construe the soul's choice of embodiment in positive terms.

There is a puzzle at the heart of Augustine's philosophical anthropology, however, that raises serious questions about how we are to construe the human condition. Depending on which of the four hypotheses one were to choose, our condition can be regarded as a divinely ordained exile and trial (the sent hypothesis), the consequence of sin conjoined with an almost immediately self-inflicted punishment (the voluntarist hypothesis), or as some kind of relatively natural habitat (the traducianist and creationist hypotheses). In the latter case, there remain questions about how to construe the soul's creation in relation to God's activity (mediated in traducianism, direct in creationism) as well as about how at home the soul is in the realm of nature.

By the time Augustine comes to write *Letter 166* to Jerome in 415, there have been significant developments in his thinking on this issue. While he does not here sharply distinguish between the two hypotheses involving pre-existence, he is clearly bothered by the cyclicism he has increasingly come to associate with pre-existence, especially as it raises the prospect of a moral landscape wherein pre-incarnate and post-mortem sins are a genuine possibility, for this would entail that that there can be no security even for those who die in a state of grace [*Letter 166*.27]. Moreover, by the time he writes Book 10 of *De Genesi ad Litteram*, (circa 415-16 C.E.) he has a further objection to the notion of pre-incarnate

sin: this possibility, he writes, is ruled out by Romans 9:11 where we are told that the souls of the unborn have done neither good nor evil [*De Genesi ad Litteram* 10.15.27]. Whether or not this poses a decisive objection pre-existence is an obscure matter. In the discussion of *De Genesi ad Litteram* 10, a version of the sent hypothesis does appear as a serious contender, but it is abruptly dropped without explanation, leaving open the question of what lies behind the sudden omission [O'Connell 1987, pp. 227-9; Mendelson 1995, pp. 242-7]. Whatever the reasons may be, the fact is that henceforward, in this text and elsewhere [e.g. *De Anima et eius Origine*, circa 419/20 C.E.], Augustine writes as if there are only two competing hypotheses of the soul's origin, the traducianist and the creationist.

Matters are further complicated by the fact that in *Letter 166* and *De Genesi ad Litteram* [see especially *Letter 166*.27], Augustine makes clear his antipathy to the traducianist hypothesis, an antipathy that, while unexplained, seems to go beyond the materialism in which Tertullian had originally cast it. Creationism, however, hardly offers an unproblematic alternative. Both *Letter 166* and *De Genesi ad Litteram* reveal concern over the question of the acquisition of original sin, an issue that becomes all the more pressing when one considers the plight of the infant who dies unbaptized [*Letter 166*.16 and *De Genesi ad Litteram* 10.11-16]. The Pelagian controversy had by this time brought to the fore the issues of grace and moral autonomy, and Augustine is now adamant in insisting upon the necessity of grace and infant baptism in the face of what he regards as Pelagian challenges to these views. In this context, the case of the infant who dies prior to baptism seems to present the hardest case of all, and the creationist hypothesis, with its direct account of the soul's relation to God's creative activity, seems singularly at a loss to address it. Augustine feels obliged to confirm, contra the Pelagians, the condemnation of the unbaptized infant, but on a creationist reading of the soul's origin, this is hard to reconcile with divine justice, especially given the notion that the unborn have done neither good nor evil. Not surprisingly, the Pelagians themselves favor the creationist hypothesis, for it seems to fit best with their views on the individual's ability to fulfill the moral obligations of the Christian life [TeSelle 1972, pg. 67; Bonner 1972 pp. 23 & 30].

It is thus, again, not surprising that there is an unofficial fifth hypothesis that can be found elsewhere in Augustine's works. In *De Civitate Dei*, for example, Augustine suggests that God created only one soul, that of Adam, and subsequent human souls are not merely genealogical offshoots (as in traducianism) of that original soul, but they are actually identical to Adam's soul prior to assuming their own individual, particularized lives [*De Civitate Dei*, 13.14]. Not only does this avoid the mediation of the traducianist hypothesis, but it also manages to provide a theologically satisfying account of the universality of original sin without falling into the difficulties of God's placing an innocent soul into a sin-laden body, as would be the case in a general creationism. To what extent this constitutes a serious contender for Augustine's attention remains a matter of controversy [O'Connell 1987, esp. pp. 11-16; Rist 1989; Rist 1994, pp 121-9; Teske 1999 pg. 810]. As noted earlier, when Augustine writes of the soul's origin in the *Retractationes* near the end of his life, he still asserts the obscurity and difficulty of the issue, and he is clearly reluctant to take a decisive stand on it. Although he sometimes downplays the seriousness of this uncertainty [e.g. *De Libero Arbitrio* III.21.59 and *De Genesi ad Litteram*, 10.20], there is no getting around the fact that it leaves a significant lacuna at the heart of his philosophical anthropology, one which leaves unanswered crucial questions about how we are to understand the embodied status of the human soul. His Neoplatonic framework commits him to the view that the physical/sensible realm is an arena of temptation and moral danger, one wherein the human soul needs to be wary about becoming too attached to lower goods.

However, Augustine's enduring ambivalence on the the question of the soul leaves open the possibility that the physical/sensible realm is more than an arena of danger and that it is in fact a fundamentally alien context, not altogether different from the Manichean view of embodiment as a kind of entrapment. The ontological unity of the Neoplatonic hierarchy notwithstanding, there appears to be room in it for a moral dualism that may be as troubling in the end as that of the Manicheans.

Psychology and Epistemology

While Augustine remains vague about how we are to understand our embodied status, there is never any question that human life is to be conceived in terms of the categories of body and soul and that an adequate understanding of the soul is necessary for an appreciation of our place within the moral landscape around us. Here Augustine is once again best understood in light of the Greek philosophical tradition [see O'Daly 1987, pp. 11-15], in which "soul" need not have any spiritual connotations. It is, instead, the principle that accounts for the intuitively obvious distinction between things that are living and things that are not. To be alive is to have a soul, and death involves a process leading to the absence of this principle. Thus, not only do human beings have souls, but so do plants and other animals [e.g. *De Libero Arbitrio* I.8; *De Quantitate Animae*, 70; *De Civitate Dei* V.10]. Augustine's view is not unlike what one finds, for example, in Plato's *Timaeus* [e.g. 89d-92c] or Aristotle's *De Anima* [e.g. 414b-415a] where different levels of soul are discussed in terms of ascending degrees of complexity in their capacities, e.g., souls capable only of reproduction and nutrition, or of sensation and locomotion as well, or finally, of rational thinking. As noted in the previous section, there is an asymmetry in these functional capacities, and reason is seen as higher than the others.

As the history of Classical Greek philosophy shows, this schema leaves open a number of possibilities in terms of the relation of soul and body (dualism, hylomorphism, and materialism, to cite some of the more obvious examples), as well as room for disagreement concerning the soul's prospect for continued existence upon the dissolution of the body (Aristotelians tended towards and Epicureans actually embraced a mortalist position, whereas Platonists and Stoics were somewhat more optimistic). For Augustine, however, it is virtually axiomatic that the human soul is both immaterial and immortal. It is worth noting in this connection that while the Christian scriptural tradition clearly alludes to the idea of post-mortem existence, the issue of the soul's immateriality is another matter. It is not obvious that the scriptural tradition requires this, and Tertullian (160-230 C.E.) is a prime example of an early Christian thinker who felt comfortable with a materialist ontology [e.g. Tertullian, *De Anima* 37.6-7]. Thus, while the immortality of the soul is arguably a point of happy convergence of these two traditions, Augustine's emphasis upon the soul's immateriality, an emphasis that comes to have enormous historical importance, seems largely a contribution of his Neoplatonism. As we have seen, he insists upon the soul's mutability as being necessary to account for moral progress and deterioration; however, it is also clear that there must be limits to this mutability, and a material soul would not only run counter to Neoplatonic ontology, but it would also impose upon the soul a degree of vulnerability that would destroy the eudaimonistic promise that made the Neoplatonic ontology so attractive in the first place.

In keeping with the intellectualism of the Greek philosophical tradition, Augustine's psychology focuses

upon the asymmetrical and dominant relation that reason is supposed to exert over other capacities. Unlike post-Humean and post-Freudian views wherein considerable attention is focused upon the role of the non-rational influences that govern our thought, Augustine takes over the ancient Greek confidence in the superiority of the rational over the non-rational. As we will see in the next section, Augustine's views on the will tend to complicate things by qualifying the extent of his intellectualism, but certainly in epistemic contexts his intellectualism tends to hold sway. In this regard, the psychological hierarchy elaborated in *De Libero Arbitrio* II [II.3-II.15] and elsewhere [e.g. *Confessions* VII.x.16 and VII.xvi.21] is a useful illustration of his view.

In the psychology that emerges in *De Libero Arbitrio* II, Augustine posits a three-fold hierarchy of things that merely exist, things that exist and live, and things that exist, live, and possess understanding [*De Libero Arbitrio* II.3]. While he elsewhere allows that plants have souls, his primary interest is in souls capable of understanding, and here, as elsewhere, he is less concerned with a neutral description of the structure of nature than with showing how the soul may find happiness by extricating itself from an overly immersed relation to nature. This being the case, Augustine's psychology tends to focus upon cognitive capacities, beginning with sense perception and working up to reason. The criteria governing the hierarchy are the relative publicity of the object of the cognitive capacity [*De Libero Arbitrio* II.7 & 14], the reliability of the capacity and its object [*De Libero Arbitrio* II.8 & 12], and, corresponding to both of these, the relative degree of immateriality and immutability of the object [*De Libero Arbitrio* II.8 & 14]. Relying upon the criterion of relative publicity, Augustine begins by noting that even among the senses there is a hierarchy of sorts, for vision and hearing seem considerably less private than both smell and taste, wherein part of the object must actually be taken into one's body and consumed during the process [*De Libero Arbitrio* II.7]. Likewise, it seems possible to see or hear the same object at the same time. In between these two extremes is the sense of touch, since two individuals can touch the same part of an object, but not at the same time. Augustine also emphasizes the fact that even in sight and hearing, the most public of the senses, one's relation to the object is always perspectival. For example, one's visual or aural relation to the object imposes limits upon how many others can have a similar relation, as well as the nature of the relation they can have. Thus, sense experience, in addition to relating to objects that are material, mutable, and hence ultimately unreliable, is also intractably private, this latter point being of considerable importance, as we will see, with respect to Augustine's theory of illumination.

The senses are coordinated by what Augustine refers to as the "inner sense" [*De Libero Arbitrio* II.3], a faculty that bears some affinities to Aristotle's common sense [see Aristotle, *De Anima* II.6]. The inner sense for Augustine makes us aware that the disparate information converging upon us from our various senses comes from a common external source (e.g., the smell and taste belong to the same object one is looking at while holding it in one's hand). The inner sense also makes us aware when one of the senses is not functioning properly. In both of these respects, the inner sense bears an organizational and criterial relation to the senses, not only combining the information of the senses, but passing judgment on the results of this synthesis. It is for this reason regarded as being above the other senses [*De Libero Arbitrio* II.5]. At this point, however, we are still at a level shared with non-rational beings. It is only when we go above the inner sense and turn to reason that we reach what is distinctively human.

As with most thinkers influenced by the Greek philosophical tradition, Augustine conceives of reason

rather austerely, focusing upon the mind's ability to engage in deductive reasoning, where logical necessity is the criterion of adequacy. The point is an important one, for it helps explain the belief that reason is distinctively human (intuitively, we may want to attribute instrumental reasoning to other species, but there is still reluctance to attribute mathematical reasoning to them), as well as our tendency to place such enormous significance upon the fact that humans are capable of reasoning. Understood in this austere sense, i.e. in terms of the mind's ability to recognize logical necessity, reason is not merely one instrument among many; instead, it becomes the means whereby the human soul comes into contact with truths that are devoid of the mutability afflicting the objects of the senses. For Augustine, reason is the cognitive apex of the human soul, not only because it distinguishes us from other creatures, but more importantly for the way it distinguishes us: it gives us access to truths that are of an absolutely reliable sort [*De Libero Arbitrio* II.8].

It is also important to note that the necessity revealed by reason is not merely logical and certainly not merely psychological. Augustine, like other thinkers influenced by the Greek tradition, saw an ontological dimension in the truths of reason, i.e., an isomorphism between the necessity that governs our thinking and the necessity that governs the structure of that about which we are thinking. It is at this point that we come upon the intersection of Augustine's psychology and epistemology, for even if we assume a kind of isomorphism between the truths of reason and the structure of being, there is an enduring historical controversy regarding what structure reason reveals as well as how the truths of reason relate to the other cognitive capacities such as sense perception and imagination.

As we have seen, from 384 onwards Augustine accepted a Neoplatonic account of the ontological and moral condition in which we find ourselves. Moreover, the psychology sketched in *De Libero Arbitrio* II and elsewhere reflects an ascending hierarchy of capacities (sense perception, inner sense, and reason), providing a psychological analogue to the ontological hierarchy. Not surprisingly, Augustine's epistemology reflects these strongly Neoplatonic tendencies, but here, as elsewhere, it would be a mistake to view Augustine's thought as an uncritical application of an inherited framework; as is often the case in other areas, Augustine's approach to epistemology is conditioned by his own religious and philosophically eudaimonistic concerns.

In particular, Augustine's epistemology seeks to exploit the psychological hierarchy with the aim of showing the reader how to navigate through the corresponding ontological hierarchy, thereby enabling us to reap the moral benefits of his Christianized Neoplatonism. This point is important, for it helps to explain why Augustine can seem, at times, so overtly indifferent towards questions that are central from the perspective of later (especially post-Cartesian) epistemology. A case in point is Augustine's treatment of Academic skepticism. As already noted, Augustine flirted with Academic skepticism, and one of his first extant works, *Contra Academicos* (circa 386 C.E.) is a focused, if at times idiosyncratic argument against Academic skepticism. Leaving aside Augustine's claim that the Academic skeptics were really Platonic realists attempting to conceal their view from those too simple to grasp its subtlety [e.g. *Contra Academicos*, 3.17.37 and *Letter 1*.1], the overall argumentative thrust of the text is nonetheless instructive [see also Kirwan, 1983].

In the *Contra Academicos*, as elsewhere, Augustine attacks skepticism as an obstacle on the road to a

eudaimonistically-construed happiness. Thus he is content to show that there are problems in the skeptic's claim to live by the likeness of truth (how can one know the likeness of x if one professes not to know x itself?) [*Contra Academicos* 2.7.16-2.8.20], and to offer a set of examples where we do have certainty regarding the truth [*Contra Academicos* 3.10.23 and 3.11.25]. What Augustine does not do is to engage in any kind of foundationalist construction of basic beliefs, nor does he attempt any kind of systematic defense of our ordinary epistemic practices so as to vindicate them in the face of skeptical attack. Even when he offers his version of what later becomes known as the Cartesian *cogito* [e.g. *De Civitate Dei* XI.26; *De Trinitate* 10.14; see also *De Libero Arbitrio* II.3 and Rist 1994, pp. 63-7], he shows no interest in using it to epistemically ground other beliefs [see Markus 1967, pp. 363-4]. Here, as elsewhere, Augustine is content to attack skepticism on a piecemeal basis [see Matthews 1972; O'Daly 1987, pg. 171; and Rist 1994, pg. 53].

Another, related, feature of Augustine's epistemology is his willingness to accept that much of our belief about the world must as a matter of practical necessity rest upon trust and authority. As he tells us in *De Magistro*, we cannot hope to verify all our beliefs about history and even many beliefs about the present are a matter of trust [*De Magistro* 11.37]. Here as elsewhere, he emphasizes the role of belief as opposed to understanding, pointing out not only that we must believe many things that we cannot understand but also that belief is a necessary condition of understanding [see *Contra Academicos* 3.20.43; *De Libero Arbitrio* II.2; and Rist 1994, pp. 56-63]. From a Cartesian foundationalist perspective, this can seem a troublingly circular view. However, we are again obliged to note that Augustine's epistemological concerns do not lie in vindicating our beliefs about the sensible world in the face of skeptical doubt, but in utilizing our non-skeptical intuitions about the sensible world to construct an accessible and rhetorically compelling account of our relation to the intelligible realm, the latter serving as the haven towards which his eudaimonism consistently points. It is worth noting, moreover, that even among those who do not share Augustine's enthusiasm for the transcendental, there are many philosophers in this century who would applaud his indifference towards Cartesian foundationalist concerns. Certainly, his views on the relation of belief, authority, and understanding are worthy of contemporary attention. But for Augustine himself, the primary concern is to lay the groundwork for what many regard as the least compelling if nonetheless most conspicuous element of his epistemology, the doctrine of divine illumination [see Markus 1967, pp. 363-73; Nash 1969; O'Daly 1987, pp. 199-207; and Rist 1994, pp. 73-9].

Augustine presents our grasp of the sensible world as grounded in a relatively unproblematic relation of direct acquaintance [e.g *De Magistro* 12.39. See also Burnyeat 1987], although there are places where his view is complicated by his Neoplatonizing conviction that the higher (e.g. the mind) cannot be affected by the lower (e.g. the body) [e.g. *De Genesi ad Litteram* XII.16 circa 415 C.E.]. In fact, he will in places explicate the mind's relation to sensible objects by means of its focusing its attention and noticing what is presented to it by the body without being causally affected by the body; in the case of physical vision, he will even go so far as to adopt the extramissionist view that a visual ray extends from the eye to the object as opposed to an intromissionist view whereby the eye passively receives something from the sensible object [e.g. *De Quantitate Animae* 23.43, circa 388 C.E.]. Even so, direct acquaintance is at some level still a necessary condition for the formation of beliefs about the external world, and the relation of the senses to sensible objects is regarded as largely unproblematic. In *De Magistro*, for example, Augustine argues that the efficacy of language is ultimately dependent upon direct acquaintance with the external

world, and even our ability to learn from others presupposes that what they tell us can be reduced to elements with which one has had some prior acquaintance [*De Magistro* 11.37]. For Augustine, as for many classical thinkers, language is a kind of third realm entity. Belonging neither to the world nor to mind, it is an instrument used by minds to communicate about the world outside them, and direct acquaintance is what explains its ability to do so. Thus, learning from others is a matter of being reminded of prior acts with which we have been directly acquainted [*De Magistro* 11.36], although this reminding can occur in such a way as to reconfigure elements from those prior acts, thus accounting for the fact that our knowledge of the world seems to be extended by such descriptions.

However odd such a model might seem, it is important to note the plausibility of some of the assumptions that underlie it: (a) language is an instrument that mediates our relation to the world and to other minds; (b) there is a distinction between signs and what they signify; and (c) our relation to the sensible world is based on direct experience. Each of these assumptions is subject to serious objections, and the past two centuries have produced ample reasons to be cautious about them. Nevertheless, they still have considerable pre-reflective currency, and for all its oddness, Augustine's suggestion that learning is a matter of being reminded of prior acts of direct acquaintance rests upon a set of common sense assumptions. This in itself is an important point, for as noted above, much of Augustine's strategy in presenting his epistemology is to exploit the relatively unproblematic nature of our relation to the sensible world, and then to reason analogously regarding our relation to the more secure, public world of intelligible objects. The question we are supposed to ponder is: given that learning is really a matter of being reminded, and given that all such occasions of being reminded depend upon acts of direct acquaintance wherein we are taught by the things themselves [*De Magistro* 12.40], what does this imply about our relation to those truths that cannot be accounted for by sense perception? In other words, if we accept this as a viable model of our epistemic relation to the external world, how do we proceed from it to explain our access to those truths whose certainty goes beyond what can be experienced in sensible objects? The traditional example here is mathematics [e.g. *De Libero Arbitrio* II.8], and in *De Libero Arbitrio* II, Augustine even argues that our ability to count presupposes a notion of unity that is empirically underdetermined [ibid]. There are, of course, other examples for Augustine besides mathematical and logical truths. Of equal importance are such truths as the awareness that all seek a happiness that goes beyond anything we have experienced in this life, that good is to be sought and evil avoided, and the awareness that there is something above and more reliable than the human mind [see *De Libero Arbitrio* II.9 and 12]. These are the kinds of examples that Augustine regards as obliging us to reject the notion that our relation to the sensible world is sufficient to account for all our beliefs and to believe that there must be more, so tospeak, to complete the picture.

That something more is provided by the doctrine of illumination, the thesis that God plays an active role in human cognition by somehow illuminating the individual's mind so that it can perceive the intelligible realities which God simultaneously presents to it. Augustine is notoriously vague as to the precise details and mechanics of this divine illumination [see, e.g. Nash 1969, pp. 94-124], and it is therefore easy to read it in an uncharitable light. Viewed without sufficient attention to the few details he provides, it can appear as if Augustine has made human cognition into a special act of divine revelation, thus making the human mind into a merely passive receptacle and God into a kind of epistemic puppeteer. For all its attendant vagueness, however, the doctrine is rather more sophisticated than it might first appear.

In the account of illumination in *De Magistro*, Augustine uses an analogy as old as Plato [see *Republic* VI.508a ff.] according to which the mind's relation to intelligible objects is like the relation of the senses to sensible objects [see *De Magistro* 12.39; see also *Soliloquia* 1.12 and O'Daly 1987, pg. 204]. In both cases, there is a need for an adventitious object to be presented to the relevant capacity, as well as the need for an environment that is conducive to the successful exercise of the relevant capacity. In the case of vision, for example, this would be light; in the case of the mind's discernment of intelligible objects, Augustine characterizes this, relying upon Platonic imagery of which Plotinus is also fond [see Plotinus, *Enneads* V.3.8 and Schroeder 1996, pp. 341-3], as an intellectual illumination that occurs within us by that which is above us. In both cases, the criterion of success is the discernment of the actual details of the object itself. Perhaps most important of all, both cases clearly allow for and rely upon acts of direct acquaintance, since illumination is, above all, meant to be an account of the conditions necessary for the mind to have direct acquaintance with intelligible objects.

Seen in this light, Augustine's view hardly seems to reduce human cognition to special acts of divine revelation [see O'Daly 1987, pp. 206-7]. Illumination is instead something that is available to all rational minds, the atheistic mathematician as well as the pious farmer measuring a field [see Rist 1994, pg. 77]. Nor does it detract from the mind's own activity and acuity, any more than a world of adventitious sensible objects detracts from the activity and acuity of the senses. In both sensory and intellectual perception, one can require a considerable degree of activity and acuity on the part of the perceiver, and in both cases one can treat failed perception as a function both of the extent to which the capacity is possessed by the perceiver and the perceiver's efforts to employ it. What sets illumination apart from more familiar cases of sense perception is that it enables us to do two related things that cannot be done by sense perception alone. First and foremost, it explains how our knowledge can have the kind of necessity that understanding (as opposed to mere belief) requires, a necessity that is always, it seems, empirically underdetermined [see, e.g. *De Libero Arbitrio* II.8 and O'Daly 1987, pp. 180-1]. In this regard, Augustine's illuminationism is a worthy contender among more familiar attempts to make intellectual cognition epistemically secure and reliable. Though it has its own difficulties, it is not clear that Augustinian illumination is all that more extravagant than Platonic recollection of a pre-incarnate existence [e.g. Plotinus, *Enneads* V.5], Aristotelian induction of particulars that somehow leads to necessary and universal truths [e.g. Aristotle, *Posterior Analytics* II.19], psychologically private Cartesian innate ideas [*Meditations*, "Third Meditation"], or Kantian transcendental idealism, wherein we are obliged to sacrifice the isomorophism of reality and thought that made necessity so attractive in the first place [e.g. *Critique of Pure Reason*, "Preface" to the First and Second Editions]. Indeed, viewed in this regard, it is not all that surprising that Augustinian illuminationism came to have the historical influence that it did, nor that Malebranche, writing some twelve hundred years later, would, in his concern with the psychologistic implications of Cartesian innate ideas, turn to Augustinian illuminationism as a model for his vision in God [see, e.g. *The Search After Truth*, Bk. II, Part Two, Chapter Six].

The second way in which illumination enables us to surpass what we are able to accomplish by means of sense perception alone is even more tightly connected to Augustine's Neoplatonizing eudaimonism. For souls which have become immersed in the sensible world and which are thereby separated from other souls by bodies, illumination is crucial to our attempt to recapture our lost unity. Unlike the perspectival and private realm of sense perception, illumination holds out the prospect of fulfilling the yearning to

which Augustine's eudaimonism gives such prominence, the yearning to find a realm wherein we can overcome the vulnerability that besets us and the moral distance that divides us from one another. Both Augustine's *Confessions* and *De Civitate Dei* in their own ways portray this sort of philosophical and spiritual pilgrimage, and one would be hard pressed to find a better example than the vision at Ostia at *Confessions* IX.10.23-25 [see "Ontology and Eudaimonism" above]. There, Augustine and his mother Monica manage, albeit fleetingly, to find themselves in a place that is clearly not in space, united in a way that overcomes the distance imposed by their mortal bodies. This unification is for Augustine the eudaimonistic conclusion through which the pursuit of knowledge is vindicated and to which it is, ultimately, to be subordinated.

Will

As already noted, a conspicuous feature of the Greek philosophical tradition is its intellectualism. Not only is nature seen as governed by patterns that are accessible to the human mind, but human agency is conceived in terms that stress the role played by reason in a life that is in keeping with the larger order [see Markus 1967 pg. 387]. Reason is an instrument that is not only capable of acts of theoretical representation, but its exercise is also regarded as being of enormous practical significance. There are, to be sure, important and powerful non-rational factors that are relevant to our actions (e.g. appetite and desire), but in a well-ordered life they are to be constrained by the dictates of reason [see e.g. Plato, *Republic* IV.441e-4441 and Aristotle, *Nicomachean Ethics* X.7.1177a10-X.9.1179a33].

As we have seen above [e.g."Ontology and Eudaimonism" & "Psychology and Epistemology"], Augustine is deeply affected by Greek intellectualism, and his own Neoplatonizing Christianity is imbued with a hierarchical structure that emphasizes the reliability of the intelligible in contrast to all that is sensible and physical. However, as Augustine's views on human agency develop, this picture is complicated by an increasing emphasis upon non-rational factors that influence our behavior and by a tendency to regard intellectualism as insufficient to explain the dynamics of human agency. Early in Augustine's career [e.g. *De Libero Arbitrio* I, circa 387/8 C.E.], there is a conspicuous emphasis on the will, and it is here that one encounters some of the most difficult and obscure aspects of his thought [see Djuth 1999, pg. 881]. Nevertheless, it marks both a significant divergence from the Greek philosophical tradition and the intersection of the philosophical and religious dimensions of his thought. Moreover, the more Augustine immersed himself in theological questions, the more prominence the nature and role of the will came to have in his writings, and his reflection upon the limited powers of the unaided will has much to do with the pessimism of his later writings.

An example of Augustine's increasing emphasis upon the will can be found in his account of his intellectual and moral transformation in *Confessions* VII-VIII. As we have seen ["Context" and "Ontology and Eudaimonism"], he credits the books of the Platonists with making it possible for him to conceive of a non-physical, spiritual reality [*Confessions* IV.xv.24; VII.i.1]. Likewise, they removed the intellectual stumbling blocks that had made it so difficult for him to accept the non-Manichean form of Christianity he found in Ambrose's Milan. However, when Augustine tells the story of his conversion in *Confessions* VII and VIII, he makes clear that although he ceased to have any genuine intellectual reservations

regarding the Church [*Confessions* VII.xxi.27 and VIII.i.1], he remained unable to commit himself to the path he could see to be the right one [see *Confessions* VII.xx.26, VII.xxi.27, and VIII.i.1]. Throughout his discussion, Augustine indicates that certainty is not the issue; he regards his predicament as falling outside the scope of intellectual assent. The ensuing discussion of his struggle is surely one of the most famous in Christian literature [*Confessions* VIII in toto, esp. VIII.viii.19-VIII.xii.30], and it is marked by a subtlety of introspective analysis that defies any easy explication. Leaving aside the question of the accuracy of his account [O'Connell 1969, pp. 4-9 and 101-104; O'Donnell 1992, vol. 3, pp. 3-4 and 55-71], it is clear that Augustine is providing a dramatic account of moral transformation, one that stresses the role of intellectual discernment while at the same time highlighting his conviction that no amount of discernment is sufficient to account for what we might refer to, for want of a better phrase, as the phenomenology of internal moral conflict. In terms of this agonistic inner turmoil, the will as both present and emergent [*Confessions* VIII.v.11 and VIII.x.22] is on an equal footing with our powers of rational discernment.

There are three distinct features that explain why the will comes to have such prominence in Augustine's thinking. In Book I of *De Libero Arbitrio*, Augustine endeavors to construct an anti-Manichean theodicy [*De Libero Arbitrio* I.2], one that accounts for the presence of moral evil in the world without either substantializing it or finding its source in divine activity. In this regard, the will is what makes an action one's own, placing the burden of responsibility on the one performing the action [*De Libero Arbitrio* I.11]. By the time he composed Book III of *De Libero Arbitrio*, however, Augustine had come to conceive of the human condition in terms of the ignorance and difficulty that attend it [*De Libero Arbitrio* III.18], and these features tend to complicate the libertarian optimism of Book I by raising questions about whether it is even possible for us to overcome the ignorance and difficulty. But even here, the will is intended to serve as the fulcrum of moral responsibility [e.g. *De Libero Arbitrio* III.22].

Though closely related, the concern with moral responsibility needs to be distinguished from the points raised in the above discussion of *Confessions* VII-VIII. In that context, Augustine is still engaged in constructing an anti-Manichean portrait of the human condition, but he is equally concerned with the aspect of agency that falls outside the scope of a purely rational or intellectual analysis. This aspect of the discussion is heightened by the fact that the choice involves a fundamental moral reorientation running contrary to habits which have acquired a necessity all their own [*Confessions* VIII.v.10], but Augustine's discussion of the example suggests that he sees it as more than an idiosyncratic or isolated incident. Rather, it is intended to draw our attention to an introspectively accessible range of phenomena that forces us to acknowledge a fundamentally non-rational component of human volition.

There is, however, a third factor at work here. The problem of evil received a rather different treatment in the non-Hellenic religious and scriptural traditions than in the Greek tradition, a contrast that was not completely lost on Augustine as he increased his familiarity with the former [e.g. *Ad Simplicianum*, circa 396 C.E. and *Confessions* VII.ix.14]. Here, one finds less emphasis upon rational analysis and logical argumentation than upon pledged community membership, trans-generational authority, obedience to divinely-sanctioned standards, and, in some cases, an overt suspicion of intellectualism together with an emphasis upon the necessity of divine aid for moral transformation. This part of Augustine's inheritance helped to divert his attention away from the strictly rational features of human agency, and to invite him to think about rationality in new ways.

While it is no doubt a mistake to compartmentalize the religious and philosophical aspects of Augustine's classical inheritance, it is often helpful to view his thought as presenting a gradual movement away from a Greek intellectualism towards a voluntarism emphasizing the profound ignorance and difficulty of the human condition, as well as the need for divine aid to overcome the ignorance and difficulty. At the heart of this shift of emphasis are Augustine's developing views on the will. Not surprisingly, this development often has to be understood against the backdrop of the philosophical and theological difficulties that come to occupy him over the years.

One of these difficulties is the relation of human free will to divine foreknowledge. While it is tempting to view this as a conflict between Athens and Jerusalem, the problem initially arises within the Greco-Roman tradition itself [see Rist 1994, pg. 268]. Although Augustine's initial treatment of the problem at *De Libero Arbitrio* III.2-4 seems innocent of this fact, his later treatment at *De Civitate Dei* V.9-10 shows that he was aware of Cicero's discussion of the problem in *De Divinatione* and *De Fato*. It is also worth noting that in later medieval philosophy, we see the mirror-image of this problem in terms of the relation of divine freedom and power versus the extent of human knowledge [see, e.g. The Condemnation of 1277; Henry of Ghent, *Quodlibet* VIII, qu.9; John Duns Scotus, *Ordinatio* I, dist. 42]. In both cases, the problem is attributable to the notion of necessity which underlies the Greek conception of knowledge. In this particular case, the problem is how to reconcile the absolute necessity that attends God's knowledge (i.e. if God genuinely knows that x is going to happen, it is impossible for x not to take place --see *De Libero Arbitrio* III.4 and *De Civitate Dei* V.9) with the idea that there can be no moral responsibility unless it is in my power to choose to do other than I in fact do [e.g. *De Libero Arbitrio* III.3]. On the surface, freedom to do otherwise seems to rule out the possibility of foreknowledge, and conversely, foreknowledge seems to rule out the possibility of freedom to do otherwise. In both *De Libero Arbitrio* and *De Civitate Dei*, Augustine's treatment of this problem is complex and at times exceedingly obscure [see Rowe 1964 and Kirwan 1989,pp. 95-103], but his aim is clear enough. Augustine is anxious, contra the Manicheans and Cicero, to defend the compatibility of divine foreknowledge and human freedom by arguing that the free exercise of the will is among the events foreknown by God and that such foreknowledge in no way detracts from our culpability for our acts of willing [e.g. *De Libero Arbitrio* III.3 & 4; *De Civitate Dei* V.9]. The obscurity of the details notwithstanding, Augustine leaves no doubt that he wants to maintain both that God does have foreknowledge of our actions and that we are morally responsible for them.

Augustine's view becomes even more complicated, however, due to theological and doctrinal concerns. While the issue of predestination is not invoked in the discussion of divine foreknowledge and human freedom at *De Civitate Dei* V.9-10 [see Rist 1994, pp. 268-9], significant developments take place between the time Augustine composes *De Libero Arbitrio* III (circa 395 C.E.) and *De Civitate Dei* V (circa 415 C.E.). In particular, there are two events that have a momentous impact upon Augustine's work in the late 390's until his death in 430. The first is his increasing familiarity with scripture and the resulting modification of his earlier, Neoplatonizing views in light of what he finds in those texts. Pivotal in this regard is *Ad Simplicianum* (396 C.E.), wherein he focuses on a number of scriptural passages and begins to formulate his views on the universality of original sin and the necessity of grace to overcome its effects [see Bonner 1972, pp. 15-18 and Babcock 1979, pp. 65-67]. The second set of events center on his

involvement in the Pelagian controversy, which occupied him from roughly 411 until his death in 430. Under the pressures of this controversy and in conjunction with his interpretation of scriptural and especially Pauline views on original sin and grace, the intellectualistic optimism of his earlier work was gradually transformed into an exceedingly grim view of the human moral landscape.

Pelagius himself is an obscure figure, as is his relation to the view that has come to bear his name (Bonner 1972, 31-35), but at the heart of the Pelagian position seems to be an emphatic insistence upon the principle that "ought implies can," i.e. that it is unacceptable to require individuals to perform actions that they cannot in fact perform [Pelagius, *Ad Demetriadem* 2, op. cit. at Brown 1967, pg. 342; see also Bonner 1972, pg. 34]. The Pelagian insistence upon preserving the kind of autonomy that seems required by the moral ideals of Christianity set in motion a fierce controversy about the nature of original sin and the role of grace in overcoming it [Brown 1967, pp.340-364]. In general, Pelagians tended to deny the kind of insuperable original sin that Augustine believed he had found in scripture, and they proposed a milder view of grace as being an aid to a will disposed to a Christian life, as opposed to being a necessary condition for such a disposition in the first place [TeSelle 1999, pg. 635]. As is often the case with disputes that have a deep moral urgency, the controversy acquired a ferocity that can seem, from a modern perspective, out of keeping with the subtlety of the points made in it, but it is precisely the sort of dispute that cannot but have lasting effects upon its participants, and Augustine was one of the main participants during the last two decades of his life.

By the time Augustine completed *De Civitate Dei* in 427 C.E., he came even more emphatically to insist upon the conclusion to which his discussion in *Ad Simplicianum* had led him, i.e., that original sin is both universally debilitating and insuperable without the aid of unmerited grace [*De Civitate Dei* XIV.1]. Furthermore, there is a predestination at work that is as rigorous as the foreknowledge by which God knows its results [*De Civitate Dei* XIV.11]. Here too Augustine insists that we are morally culpable for the sinful choices that the will makes [*De Civitate Dei* XIV.3], but under the pressures of the Pelagian controversy -- a controversy in which he will find his earlier words being cited against him [see *Retractationes* I.9.3-6] -- he presents these views in a manner that is austere and uncompromising. So damaging are the effects of the original sin that the human will is free only to sin [*De Correptione et Gratia* 1.2; 11.31; Rist 1972, pg. 223]. Thus, the human race is comprised of a *massa damnata* [*De Dono Perseverantiae* 35; see also *De Civitate Dei* XXI.12], out of which God, in a manner inscrutable to us [*De Civitate Dei* XII.28], has predestined a small number to be saved [*De Civitate Dei* XXI.12], and to whom he has extended a grace without which it is impossible for the will not to sin. While there is some controversy over whether this grace is sufficient for redemption and whether it can be resisted [Rist, 1972, pp. 228ff.], Augustine makes clear that it is as much a necessary condition as it is unmerited and inscrutable. The ignorance and difficulty that afflict our condition in *De Libero Arbitrio* III have become more than obstacles to be overcome by means of our will [*De Libero Arbitrio* III.22]; they are now impassible barriers we have inherited from Adam, and without unmerited grace we are utterly incapable of initiating even the smallest movement away from sin and towards God. In *De Libero Arbitrio* I, Augustine suggests that the will is confronted by a rational choice between a life spent in the pursuit of what is temporal, changing, and perishable, and a life spent in the pursuit of what is eternal, immutable, and incapable of being lost [*De Libero Arbitrio* I.7]. By the time he comes to write *De Gratia et Libero Arbitrio* in 426 C.E., in the midst of the Pelagian controversy, we find a vastly different picture. Here too

the will is central, and here too we are culpable for our sins, but gone is the earlier optimism. The post-Adamic will is no longer in a position to initiate any choice of lives; the fact that we have any choice at all is entirely a product of unmerited grace [see, e.g. *De Gratia et Libero Arbitrio* xx and xxi], a grace that will be given to only a small number whom God has predestined to be saved out of the vast number who are eternally lost.

Being more a matter of theology than philosophy, it can be tempting for those interested in Augustine as a philosopher to turn away from his later thinking on the will, but one has to be careful in doing so. To begin with, the boundary between the philosophical and the theological is not as clear in Augustine as it is in later philosophers, and part of what makes Augustine such a fascinating thinker is his refusal to compartmentalize his thought in ways that are now taken for granted. Second, the development of Augustine's thinking on the will, as unsettling as the resulting moral landscape may be, does oblige one to confront questions about what a viable concept of the will should involve as well as questions about how to determine moral culpability in the face of external determination -- questions that are as easy to overlook as they are difficult to address. Finally, Augustine's reflections on the will had considerable influence upon those who inherited his vast legacy and on his own account of how we are to understand the drama of human history.

History and Eschatology

It is an irony that the man who bequeathed a Neoplatonic world view to the West also gave us a way of conceptualizing human history that is at odds with some of its most basic contours. In the Greco-Roman world in general and in Neoplatonism in particular, the importance of history is largely in the cyclical patterns that forge the past, present, and future into a continuous whole, emphasizing what is repeated and common over what is idiosyncratic and unique. In Augustine, we find a conception of human history that in effect reverses this schema by providing a linear account which presents history as the dramatic unfolding of a morally decisive set of non-repeatable events.

For the present day reader, it is easy to overlook both the plausibility of the cyclical view and the sorts of considerations that might stand in the way of the linear model with which we have become more familiar. Not only are there the obvious patterns of the seasons and the regularities discernible in astronomical phenomena, but, at a deeper level, there is the indispensable role that regularity and the recognition of common features play in our efforts to make the world intelligible. Moreover, the emphasis upon the common-qua-universal is a conspicuous feature of the Greek philosophical tradition. Thus, it is also hardly surprising that we find Aristotle telling us that poetry is more philosophical than history because it is more clearly concerned with universals, whereas history tends to be more concerned with particulars [Aristotle, *Poetics* 9.1451b1-7]; nor is it surprising that Thucydides presents his account of the Peloponnesian War as providing a pattern of events that will be repeated in the future [Thucydides, *History of the Peloponnesian War*, I.22]; or that Plutarch recounts past lives in a manner clearly designed to draw the reader's attention to patterns of virtue and vice rather than to faithfully recount particular facts [see, e.g. Plutarch, *Life of Pericles* 1.1-2]; or, for that matter, that Augustine himself would tell the tale of his first thirty-two years in the way that he does, more concerned to capture the Neoplatonic drama of the

soul's immersion and extraction from the sensible/physical world than with providing a factual account of dates, names, and places.

Approached from this angle, what wants an explanation is why one would subordinate indispensable patterns and regularities in order to emphasize what is idiosyncratic and unique . Here, as in the case of the will, it is important to understand that Augustine is bringing together two quite disparate traditions, and here again one needs to take note of his efforts to capture the data of revelation he sees embedded in Judeo-Christian scripture. If one approaches these latter texts as presenting a Christian drama of the soul's salvation, one cannot help but focus upon the unique, non-repeatable events that define the drama, e.g., the fall recounted in the early chapters of Genesis, the incarnation, passion, and resurrection of Christ in the synoptic and Johannine gospels, and the final judgement foretold in Revelations. One must, however, exercise some caution here. The cyclical and linear approaches are matters of emphasis rather than mutually exclusive alternatives, and the scriptural traditions upon which Augustine relies are certainly not devoid of cyclical motifs [e.g. Ecclesiastes 3.1-8], nor does Augustine himself embrace one approach wholly to the exclusion of the other, as even a cursory reading of his *Confessions* reveals. And, of course, the historically unique life of Christ becomes a pattern for the Christian life in general [e.g. *De Civitate Dei* XXII.5]. These points notwithstanding, there can be little question that Augustine provides an account of human history that is at times resolutely linear, a tendency which can be traced to the Judeo-Christian scriptural tradition.

Already in *De Magistro* (389 C.E.) Augustine is keenly aware that much of what we need to believe falls outside the austere standards of his Platonic conception of knowledge and understanding. Among the most prominent of these are beliefs based on scripture [*De Magistro* 11.37; cf.12.39]. In the *Confessions* as well, even when Augustine is especially laudatory of the Platonists, he is emphatic that there is much that these books leave out. They cannot, for example, speak about those historical truths definitive to the Christian view of redemption through the incarnation and passion of Christ [*Confessions* VII.ix.13-14; see Bittner 1999, pg. 346]. Augustine is acutely aware that scripture has an historical dimension, and he is sensitive as well to the tensions between the scriptural tradition and the Neoplatonic framework upon which he is relying, a tension that comes to eclipse much of the intellectualistic optimism we find in his earliest completed post-conversion works, e.g. the *Contra Academicos* of 386 C.E. [see *Contra Academicos* 3.20.43 and "Context" above].

As we have seen, Augustine's increasing familiarity with the contents of scripture leads him to focus more and more upon the historical dimension of this tradition, a dimension alien to the intellectualism of the books of the Platonists. We have already seen this development reflected in his interest in the fall and the subsequent necessity of grace set forth in the *Ad Simplicianum* of 396 C.E. But it is in Augustine's sprawling *City of God* [*De Civitate Dei*, 413-427 C.E.] that one finds his most extensive and focused treatment of human history [see Rist 1994, pp. 203-255]. It is important to bear in mind, however, that Augustine does not provide a philosophy of history of the sort that one might find in a Vico, Hegel, or Marx; his concern is not with articulating a notion of history that views its progress as intelligible, or that sees it as developing according to immanent processes that are themselves accessible and worthy of study. Human history, for Augustine, is subsumed by the larger context of an eschatology wherein history is the temporal playing out of a divine justice in which the end is as fixed as the beginning [see Bittner 1999, pg.

348]. While it is not for us to know all the details of the plot or its conclusion [*De Civitate Dei* XX.2], we can nonetheless discern the general direction of the drama, as well as the juridical nature of the conclusion at which aims.

The drama is, for the most part, a hauntingly somber one. Due to the universal contagion of original sin wherein all have sinned in Adam, humanity has become a mass of the deservedly damned [*De Civitate Dei* XXI.12] who have turned away from God and towards the rule of self [see *De Civitate Dei* XIII.14; XIV.3 & 13]. By means of an utterly unmerited grace, God has chosen a small minority out of this mass -- the smallness of the number is itself a means whereby God makes apparent what all in fact deserve [*De Civitate Dei* XXI.12] -- and thus human history is composed of the progress of two cities, the city of God and the city of Man [e.g. *De Civitate Dei* XIV.28; XV.1 & 21; see Cranz 1972]: those who by means of grace renounce the self and turn towards God, as opposed to the vast majority who have renounced God and turned towards the self [*De Civitate Dei* XIV.28]. In this life, we can never be sure of which individuals belong to which city [e.g. *De Civitate Dei* XX.27], and thus they are intermingled in a way that thwarts any moral complacency. While the visible church bears a special relation to the city of God, membership in the Church is no guarantee of salvation [e.g. *De Civitate Dei* XX.9], and the history that is visible to us is merely a vestige of the moral drama that takes place behind the scenes, defying the scrutiny of our weak and often presumptuous reason [*De Civitate Dei* XX.21 & 22]. Whatis certain is that the linear movement of human history aims at the eventual separation of the two cities [e.g. *De Civitate Dei* XX.21 & 28], in which the members of each city are united with their resurrected bodies [e.g *De Civitate Dei* XXI.1 & 3 and XXII.21] and given their respective just rewards: for the small minority saved by unmerited grace, there is the vision of God, a joy we can only dimly discern at the moment [*De Civitate Dei* XXII.29]. For the overwhelming mass of humanity, there is the second death wherein their resurrected bodies will be subject to eternal torment by flames that will inflict pain without consuming the body [*De Civitate Dei* XXI.2-4], the degree of torment proportional to the extent of sin [*De Civitate Dei* XXI.16], although the duration is equal in all cases: they must suffer without end, for to suffer any less would be to contradict scripture and undermine our confidence in the eternal blessedness of the small number God has saved [*De Civitate Dei* XXI.23].

In *De Civitate Dei* as in the earlier *Contra Academicos*, Augustine is a eudaimonist who enjoins us to seek a happiness understood in terms of our objective relation to an hierarchical structure [e.g. *De Civitate Dei* XIV.25 and XX.21], and he still invokes philosophy, rightly understood, as an instrument that can help us move towards this end [*De Civitate Dei* XXII.22]. Moreover, he still views the world we experience as only a small part of reality, and here too Augustine sees our earthly lives as perfected in a realm that is outside the flux of history as we know and experience it [*De Civitate Dei* XXI.26]. Much, however, has obviously changed. Gone is the confidence that the "harbor of philosophy" [e.g. *Contra Academicos* 2.1.1] is the haven wherein we can find the rest that we seek, and gone is the idea that the rational life will lead us to our eudaimonistic end; gone as well is the breathless excitement with which Augustine would enjoin others to pursue the life of rational enquiry [e.g. *Contra Academicos* 2.2.5]. In place of all this is a moral landscape that seems even sadder and more unsettling than the sense of loss it was originally intended to relieve. And yet, even at the very end of *De Civitate Dei*, Augustine makes clear that he still regards this as a landscape which holds out the prospect of an incomparable vision and rest from all anxiety, a renewed condition that defies all mortal estimation [*De Civitate Dei* XXII.30; see also XX.21].

Now the aging Bishop of Hippo, Augustine still shows a trait he first exhibited as a youthful convert at Cassiciacum: a keen sense of the moral darkness that surrounds us and a philosophical penchant for the unexpected turn of thought by which he would have us escape it.

Legacy

In the long and difficult controversy with the Pelagians, Augustine found his own earlier writings on the will cited by his opponents as evidence that he himself once advocated the view he came so vehemently to oppose [see *Retractationes* I.9.3-6]. What is more, he dies just as the Vandals are besieging the gates of Hippo, leaving unfinished yet another work against Julian of Eclanum, a Pelagian opponent of considerable intellectual resources who had, among other things, accused Augustine of holding views indistinguishable from those of the Manicheans whom Augustine had opposed so many years before [Bonner, 1999]. And here, perhaps, is an irony as cruel as it is intriguing: eleven centuries later, when the Church to which Augustine had devoted the last four and a half decades of his life was to split in a manner that still shows no signs of reconciliation, both sides would appeal to Augustine as an authority on questions of doctrine [Muller 1999; Grossi 1999].

Leaving aside the relative merits of these accusations and appeals, their mere existence is only possible because of the diversity and astonishing range of Augustine's thought over the course of his lifetime. Augustine's movement from a largely Hellenistic eudaimonism to the increasingly somber eschatology of his later works is much more than a mere shift of position. It is the emergent product of a mind continually immersed in controversy and ever obliged to rethink old positions in light of new exigencies, obliged to turn yet again the stone turned so many times before.

First and foremost in Augustine's legacy is the voluminous body of work that encompasses this movement, revealing a range of thought only a handful of philosophers have managed to achieve. The diversity contained in this body of work defies any easy or succinct synopsis, and anyone who approaches it will find a range of ideas that can alternately intrigue, surprise, and sometimes even disarm and shock. One will also find a range of genres and styles, ranging from texts crafted with great rhetorical subtlety to texts that seem to "jangle" with the "music" [O'Connell 1987, pg. 203] of one who is thinking aloud as he writes. For those who want arguments and evidential support, it is there to be had, sometimes in repetitive abundance; for those sensitive to and appreciative of the power of poetic imagery, that too is abundantly in place. Indeed, as Robert O'Connell says, "Augustine constructed more through a play of his teeming imagination than by the highly abstract processes of strict metaphysical thinking" [O'Connell 1986, pg. 3].

But if that vast, multifaceted corpus is the basis of Augustine's legacy, it is also the ultimate obstacle to any attempt at neatly packaging or compartmentalizing it within some "ism" that can be neatly taxonomized. This is, of course, true of most major philosophers, but it seems incontestably true of Augustine. In place of tidy boundaries, there is instead the "jangle" of the corpus itself and the enormous influence it comes to have. This influence is to be found, for example, throughout early medieval philosophy (e.g. Boethius and John Scotus Eriugena), and in Anselm of Canterbury, including in what later came to be known as the ontological argument [*Proslogion*, Chapters I-IV]. Augustine's influence is

plainly discernible in Bonaventure [e.g. *Itinerarium Mentis in Deum*] and others in the thirteenth century who sought an alternative to the Aristotelianism then gaining currency (e.g. John Peckham and Henry of Ghent). Even Thomas Aquinas, a pivotal figure in the rise of Aristotelianism, takes care to address and to accommodate Augustine's view on illumination among many other issues. In the modern period, the echoes in Descartes are conspicuous, both in the *cogito* [Matthews 1992] and elsewhere [Matthews 1999b]. And, of course, few philosophers have invoked Augustine as explicitly and as frequently as Malebranche [see, e.g. "Preface" to *The Search After Truth*]. More recently, one of the most influential works of twentieth century philosophy, Wittgenstein's *Philosophical Investigations*, opens with a lengthy quotation from Augustine's *Confessions* and a discussion of the picture of language that Wittgenstein sees invoked in it [Wittgenstein, *Philosophical Investigations*, Part I, pars 1-3 & 32]. And if this selective historical sampling were not enough, there is an enormous body of secondary literature devoted to Augustine ranging across disciplinary boundaries and across divisions within the philosophical community itself. In 1999 alone, there appeared, among numerous other works, a 900 page encyclopedia devoted to Augustine as a religious and philosophical figure [Fitzgerald, 1999] and a volume of essays by several prominent philosophers in the analytic tradition exploring Augustine's relation to a variety of topics including consequentialism, Kantian moral philosophy, and just war theory (an important issue which unfortunately falls outside the scope of the present discussion) [Matthews 1999]. If one examines the diverse interests of those influenced by Augustine together with the enormous body of secondary literature on Augustine, one finds again what one cannot fail to discern in the Augustinian corpus itself: a diversity as amazing as it is broad, one that defies any attempt at neat summary or tidy explication, a diversity as rich as it is discordant. It is unlikely that this is the legacy that Augustine would have wanted to leave behind, but it is a legacy of a sort that only a handful of philosophers have managed to achieve. The obvious irony notwithstanding, the discordance and diversity are both measures of, and testimony to, an intellectual depth and range seldom equalled in the history of western philosophy.

Bibliography

Selected Latin Texts and Critical Editions

The most common and most complete (but uncritical) edition of Augustine in Latin is the seventeenth century Maurist edition of Augustine's *Opera Omnia* which is reprinted in volumes 32-47 of J.P. Migne's *Patrologiae Cursus Completus*, *Series Latina* (Paris 1844-64), referred to below as **PL**. More critical texts are gradually emerging in four main series:

- *Corpus Scriptorum Ecclesiasticorum Latinorum*, Vienna: Tempsky, 1865- [**CSEL**]
- *Corpus Christianorum*, *Series Latina*, Turnhout: Brepolis, 1953- [**CCL**]

- *Bibliotheque Augustinenne, Oervres de Saint Augustin*, Paris: Desclee De Brouwer, 1949- [**BA**]
- *Nuova Biblioteca Agostiniana*, *Opera de S. Agostino, edizione latino-italiana*, Rome: Citta Nuova 1965- [**NBA**]

Given the voluminous number of Augustine's texts, the following list is confined to those especially relevant to the present article. In what follows, the Migne volume [**PL**] will be provided as well as those of any of the other above editions that have appeared. For information on Augustine texts not listed here, the reader is referred to Fitzgerald 1999, pp. xxxv-xlii, and the reader can also feel free to contact the author via the email address listed at the end of this article.

- *De Beata Vita* (*On The Happy Life*), circa 386/7 C.E.: **PL**32; **CSEL**63 (1922); **CCL**29 (1986); **NBA**3 (1970).
- *Contra Academicos* (*Against the Skeptics*), circa 386/7 C.E.: **PL**32; **CSEL**63 (1922); **CCL**29 (1970); **BA**4 (1939); **NBA**3 (1970).
- *Soliloquia* (*Soliloquies*) circa 386 C.E.: **PL**32; **CSEL**89 (1986); **BA**5 (1939); **NBA**3 (1970).
- *De Libero Arbitrio* (*On Free Will*) Book I circa 386/8 C.E., Books II-III, circa 391-5: **PL**32; **CSEL**74 (1956); **CCL**29 (1970); **BA**6 (1952); **NBA**3/2 (1976).
- *De Magistro* (*On The Teacher*) circa 389 C.E.: **PL**32; **CSEL**77 (1961); **CCL**29 (1970).
- *Ad Simplicianum* (*To Simplicianus*) circa 396 C.E.: **PL** 40; **CCL**44 (1970).
- *Confessiones* (*Confessions)* circa 397-401 C.E.: **PL**32; **CSEL** (1896); **CCL**27 (1981). See also O'Donnell 1992, volume 1 in "Selected Secondary Works" below.
- *De Trinitate* (*On The Trinity*) circa 399-422/6 C.E.: **PL** 42; **CCL** 50/50A.
- *De Genesi ad Litteram* (*On The Literal Meaning of Genesis*) circa 401-415 C.E.: **PL**42; **CSEL**28/1.
- *De Civitate Dei* (*On The City of God*) circa 413-427 C.E.: **PL**41; **CSEL**40; **CCL**47-8.
- *Retractationes* (*Retractations*) circa 426/7 C.E.: **PL**32; **CSEL**36 (1902); **CCL**57 (1984); **BA**12 (1950); **NBA** 2 (1994).
- *Epistulae* (*Letters*) circa 386-430 C.E.: **PL**33; *Ep*. 1-30: **CSEL**34/1 (1895); *Ep*. 31-123: **CSEL** 34/2 (1898); *Ep*. 124-84A: **CSEL**44 (1904); *Ep*. 185-270: **CSEL** 57 (1923); Recently discovered *Ep*.: 1*-29* **BA**46B (1987).

Selected English Translations

The following list is of standard and available English translations of the works cited above. Again, there is no attempt to be exhaustive, and readers seeking information for titles not listed should consult the relevant entry in Fitzgerald 1999 or contact the author via the email address at the end of this article.

- *De Beata Vita* is translated in *The Works of Saint Augustine: A Translation for the 21st Century*, vol 1.3, New City Press, 1990-.
- *Contra Academicos* is translated in *Against the Academicians and The Teacher*, translated by Peter King, Hackett Publishing Company, 1995
- *Soliloquia* is translated in *Soliloquies*, Library of Christian Classics, volume 6, 1953.
- *De Magistro* is translated in *Against the Academicians and The Teacher*, translated by Peter King,

Hackett Publishing Company, 1995

- *Ad Simplicianum* is translated in *The Works of Saint Augustine: A Translation for the 21st Century*, vol. 1.12, New City ress 1990-
- *Confessiones* are translated in *Confessions*, translated by Henry Chadwick, Oxford University Press, 1991.
- *De Trinitate* is translated in *The Works of Saint Augustine: A Translation for the 21st Century*, vol. I.5, New City Press 1990-
- *De Genesi ad Litteram* is translated in *St. Augustine: The Literal Meaning of Genesis*, translated by John H. Taylor, Ancient Christian Writers, vol 41-2, Newman Press 1982.
- *De Civitate Dei* is translated in *The City of God Against the Pagans*, translated by R.W. Dyson, *Cambridge Texts in the History of Political Thought*, Cambridge University Press 1998.
- *Retractationes* is translated in *The Works of Saint Augustine: A Translation for the 21st Century*, vol. I.2, New City Press 1990-
- *Epistulae* are translated by W. Parsons in the *Fathers of the Church* series: Letters 1-82, vol 12; Letters 83-130, vol. 18; Letters 131-64, vol. 20; Letters 165-203, vol. 30; Letters 204-70, vol. 32; recently discovered Letters *1-*29 are translated by R. Eno in vol. 81.

Selected General Studies

The following is a list of works that can be helpful as introductions, guides, or general studies of Augustine's thought. The list represents a variety of viewpoints and approaches to Augustine, but it makes no attempt at being exhaustive. Interested readers should also consult Markus 1967 in "Select Secondary Works" below. The author welcomes suggestions for further additions.

- Bonner, Gerald (1986): *Augustine of Hippo: Life and Controversies*, Canterbury Press 1986.
- Brown, Peter (1967): *Augustine of Hippo: A Biography*, University of California Press 1967.
- Chadwick, Henry (1986): *Augustine*, Past Masters Series, Oxford University Press 1986.
- Clark, Mary T.(1994): *Augustine*, Georgetown University Press 1994.
- Fitzgerald, Allan D. (ed.) (1999): *Augustine Through the Ages: An Encyclopedia*, William B. Eerdmans Publishing Company, 1999.

Divine Illumination

Divine illumination is the oldest and most influential alternative to naturalism in the areas of mind and knowledge. The doctrine holds that human beings require a special divine assistance in their ordinary cognitive activities. Although most closely associated with Augustine and his scholastic followers, the doctrine has its origins in the ancient period and would reappear, transformed, in the early modern era.

Orientation

The theory of divine illumination is generally conceived of as distinctively Christian, distinctively medieval, and distinctively Augustinian. There is some justification for this, of course, inasmuch as Christian medieval philosophers gave the theory serious and sustained discussion, and inasmuch as Augustine gave illumination a very prominent role in his theory of knowledge. Still, it is better to think of the theory in a wider context. Divine illumination played a prominent part in ancient Greek philosophy, in the later Greek commentary tradition, in neo-Platonism, and in medieval Islamic philosophy. Moreover, it was Christian medieval philosophers, near the end of the thirteenth century, who were ultimately responsible for decisively refuting the theory. I will suggest that we view this last development as the first great turning point in the history of cognitive theory.

I understand a theory of divine illumination to be a theory on which the human mind regularly relies on

some kind of special supernatural assistance in order to complete (some part of) its ordinary cognitive activity. The assistance must be *supernatural*, of course, or it will not count as *divine* illumination. It must be *special*, in the sense that it must be something more than the divine creation and ongoing conservation of the human mind. (If the latter were to count as illumination, then all theists would be committed to the theory of divine illumination.) The mind must *regularly* rely on this assistance, in order to complete its *ordinary* cognitive activity: otherwise, an occasional mystical experience might suffice to confirm a theory of divine illumination. But a defender of the theory need hold only that we require this assistance for *some part of* our ordinary cognitive activities: hardly anyone has supposed that every form of human cognition requires divine illuimination.

It is useful to think of divine illumination as analogous to grace. Just as a proponent of grace postulates a special divine role on the volitional side, so a proponent of divine illumination postulates a special divine role on the cognitive side. Grace is intended as an explanation not of all human desires and motivations, nor even of all virtuous desires and motivations. Rather, the proponent of grace holds that there is a certain class of volitional states, crucial to human well-being, that we can achieve only with special divine assistance. Likewise, the theory of divine illumination is intended as an explanation not of all belief, nor even of all knowledge. Rather, the theory holds that there are certain kinds of knowledge, crucial to cognitive development, that we can achieve only with special divine assistance. It is an odd fact that, despite the close analogy, grace is regarded not as a philosophical question, but as a theological one. It is an equally odd fact that, whereas divine illumination hasn't generally been regarded as plausible since the thirteenth century, grace continues to be taken seriously by many theologians. Perhaps both of these facts can be accounted for by motivational psychology's relative obscurity in comparison to cognitive psychology.

For most people today it is hard to take divine illumination seriously, hard to view it as anything other than a quaint relic. A first step toward developing a proper perspective on the theory is to see it in its broader context, not as peculiarly Christian or medieval, but as an assumption shared by most premodern philosophers. A second step in the same direction is to identify and to take seriously the philosophical problem that drives illumination theory. In large part, the theory has been invoked to explain rational insight -- that is, a priori knowledge. Recent philosophers, preoccupied with empirical knowledge, have not had much interest in this topic. (A recent notable exception is Bonjour 1998.) But to see how something like divine illumination could have ever seemed at all plausible, one has to see how deeply puzzling the phenomenon of rational insight actually is. One way of seeing this, and of seeing how little we understand rational insight, is to look at cases where something goes wrong. A recent biography of the Nobel-prize winning mathematician John Nash describes his long period of mental illness, during which time he held various odd beliefs such as that extraterrestrials were recruiting him to save the world. How could he believe this, a friend asked during a hospital visit, given his devotion to reason and logic?

> "Because," Nash said slowly in his soft, reasonable southern drawl, as if talking to himself, "the ideas I had about supernatural beings came to me the same way that my mathematical ideas did. So I took them seriously" (Nasar 1998, p.11).

In a case such as this we don't know what to do, because we are accustomed to give unhesitating trust to the deliverances of pure reason. But why should we trust reason in this way? Why should we have confidence that others can come to share our insights? Where does it come from? The theory of divine illumination attempts to answer such questions.

The Ancient Background

What follows is by no means a comprehensive survey. Still, it seems useful to begin near the beginning, with this remark by Socrates from the *Apology*:

> I have a divine or spiritual sign which Meletus has ridiculed in his deposition. This began when I was a child. It is a voice, and whenever it speaks it turns me away from something I am about to do, but it never encourages me to do anything (31d, tr. Grube).

This appears to be an entirely straightforward expression of a theory of divine illumination. It is not clear who is providing the illumination. Apuleius (fl. 150 CE) would later identify the source as a certain kind of friendly demon, and argue that it was only fitting for Socrates, the most perfect of all human beings, to receive such illumination (*De deo Socratis*, XVII-XIX). (This idea that illumination comes to those who deserve it would be proposed by Augustine as well [e.g., *De magistro* 11.38], but abandoned in his later writings as untenable.) As one might expect from Socrates, his illumination seems restricted to the moral sphere. Its form is unclear: is it propositional? (see *Phaedrus* 242bc) Is it merely the pang of conscience? (For discussion of these and other questions, see McPherran 1996.) Whatever the details, Socrates is explicitly describing a kind of cognitive guidance that has a "divine or spiritual" source. The passage may be an embarrassment to classicists, but it surely belongs in the same tradition as later medieval endorsements of illumination.

Not all appeals to the divine involve this sort of direct communication. (Indeed, Socrates's reference to a "voice" is quite extraordinary.) But the leading figures in ancient Greek philosophy were equally committed to some kind of divine role in cognition. Plato's theory of recollection presupposes that the human mind somehow has built into it a grasp of the Forms, suggesting that at some point the soul must have received some kind of illumination. Indeed, Plato's arguments for recollection anticipate the two lines along which medieval views would later develop. The *Meno* focuses on a priori, rational insight, as illustrated by the slave's ability to see for himself the validity of a geometrical proof. The *Phaedo* in contrast focuses on universal properties -- Equality, for instance, as compared with two equal sticks (74a) -- contrasting the changeable imperfection of the physical world with the exemplary perfection of the Forms. Medieval philosophers from Augustine on, although largely lacking in firsthand knowledge of Plato, would argue for illumination along both of these lines.

Aristotle too seems to invoke the divine. He describes the active intellect in this way:

> This intellect is separate, unaffected, and unmixed, being in essence activity.... It is not the

> case that it sometimes thinks and at other times not. In separation it is just what it is, and this alone is immortal and eternal (*De anima* III 5, 430a17-23).

There is of course unending controversy over the meaning of this text. One very common reading, in ancient times and our own, is that this active intellect is something divine, not a human faculty at all. If one then makes the further, natural assumption that the active intellect participates in ordinary human cognition, then Aristotle would clearly be committed to a version of divine illumination. (One should, however, be cautious in supposing that Aristotle's *nous poietikos* plays anything like the role played by the scholastic *intellectus agens*. See Haldane 1992.) Not everyone has been persuaded that this active intellect is something literally separate and divine. But even if one supposes that the active intellect is a part of the human soul, it is nevertheless difficult to avoid the suspicion that some sort of special divine influence is at work. Everything in the passage cries out for some sort of supernatural element in human cognition.

Alexander of Aphrodisias (fl. 200 CE) was influential in pushing the separate-and-divine reading of *De anima* III.5, and Islamic philosophers (most notably Avicenna [980-1037] and Averroes [c.1126-c.1198]) would later follow suit. Themistius (4th century CE), in contrast, championed the part-of-soul reading, and Thomas Aquinas (1225-1274) would second this interpretation. A full treatment of this topic would cover the later Aristotelian and Platonic traditions, Greek and Islamic. But here I will focus exclusively on the Latin West, where it was Augustine who played the decisive role in formulating the doctrine of illumination. (For a useful survey of ancient and medieval Aristotelian accounts of agent intellect, see Brentano 1992. On the later Platonic tradition, see Gersh 1978. The Islamic tradition deserves a full essay in its own right, covering not just names well known in the Latin West, but also figures like Suhrawardi and Mulla Sadra, central figures in the Islamic illuminationist tradition [see Fakhry 1983].)

Augustine

Throughout his long literary career, Augustine (354-430) stresses the role of divine illumination in human thought. One could choose almost any work to illustrate this point; here I will focus on the most familiar of all, the *Confessions*, where Augustine invokes divine illumination constantly, and makes bold claims for its global necessity:

> The mind needs to be enlightened by light from outside itself, so that it can participate in truth, because it is not itself the nature of truth. You will light my lamp, Lord (IV.xv.25).
>
> None other than you is teacher of the truth, wherever and from whatever source it is manifest (V.vi.10).
>
> You hear nothing true from me which you have not first told me (X.ii.2).
>
> Truth, when did you ever fail to walk with me, teaching me what to avoid and what to

> seek.... Without you I could discern none of these things (X.xl.65).

Even during the Middle Ages, Augustine's readers disagreed on the precise nature of his theory. One thing that seems clear from these passages alone is that divine illumination is an influence that we receive in an ongoing way throughout our lives. Thomas Aquinas would later understand illumination as an infusion all at once at the start (see below), but this seems untenable as an interpretation of Augustine. The mind needs to be enligtened "from outside itself"; "it is not itself the nature of truth"; "you *will* light my lamp, Lord" (he has not done so already); truth "walk[s] with me," rather than merely setting me in motion at the start.

To speak of this influence as an illumination is of course to use a metaphor, one not likely to be unpacked fully. Our own minds present enough of a puzzle to us: when we try to understand how the divine mind might influence our own, we must inevitably fall back on metaphor. Still, there are a variety of ways in which we might seek some clarification. In particular, it is helpful to distinguish two ways in which God might provide illumination. First, he might simply give us information of certain kinds, telling us how things are. This is how illumination is most often understood, at least implicitly. But a second possibility is that God would provide not the information itself, but the insight into the truth of the information. On this second model, we would frame beliefs on our own, and God would illuminate our minds so that we could see the truth. In other words, God would supply the justification. It is clear that sometimes illumination takes the first form: much of Biblical revelation just is illumination in this sense. But Augustine's theory of illumination seems largely to be of the second kind. Consider this famous passage from the *Confessions*:

> If we both see that what you say is true, and we both see that what I say is true, then where do we see that? Not I in you, nor you in me, but both of us in that unalterable truth that is above our minds (XII.xxv.35).

At issue here is Biblical interpretation. When a reading is advanced that seems clearly correct, how is it that everyone listening grasps the truth of that reading? It is not that God gives us the interpretation itself, but that he allows us to see that the interpretation is true.

This understanding of illumination is particularly apparent in the *De magistro*, where Augustine argues that only God can teach us. Of course, other people can tell us things, and can thereby communicate ideas to us. And we can believe what others tell us: indeed, our lives would be impoverished if we didn't regularly accept what others tell us. But all of this stays at the level of mere belief. It is not knowledge unless we grasp with our minds the truth of what we are hearing:

> When I speak the truth, I do not teach someone who sees these truths. For he is taught not by my words but by the things themselves made manifest within when God discloses them (12.40).

The speaker's role is not irrelevant in this process. My words give the listener an idea that he can then

verify for himself in light of God's illumination. Illumination is what allows us to go from mere true belief to knowledge. Illumination provides justification.

This account is most attractive in cases of a priori knowledge or pure reasoning, where we grasp through the mind alone that an argument is valid or that a conclusion is necessary. But there is another strain of thought running through Augustine, one that focuses on the mind's ability to transcend the untrustworthy senses and grasp the truth that lies beyond mere appearances. The following passage is very often cited in this connection:

> Everything that the bodily senses attain, that which is also called sensible, is incessantly changing.... But what is not constant cannot be perceived; for that is perceived which is comprehended in knowledge. But something that is incessantly changing cannot be comprehended. Therefore we should not expect pure truth from the bodily senses (*De diversis quaestionibus octoginta tribus*, q.9).

In one stroke, this argument rules out the physical world as an object of pure truth, and rules out the senses as a source for that truth. It must be the mind, then, with which we attain truth, and that truth must be something beyond the sensible world. Plainly, the mind cannot rely on the senses. But what else is there? The conclusion we are invited to reach is that the mind must rely on God.

One might try assimilating this line of thought to those passages where Augustine has in mind necessary a priori truths. But it is more natural to take this in a different way, as an account of how the mind goes beyond the sensible data to a grasp of the real essences of things. Accordingly, the theory of divine illumination would be put to two very different sorts of work in the later Middle Ages: as an account of a priori knowledge, and as an account of concept formation. Each account raises its own set of issues. Taken in the first way, divine illumination has to compete against the claim that the mind is naturally capable of grasping such truth. Taken in the second way, questions immediately arise about the nature of conceptual knowledge. Do essences (or properties in general) exist in the physical world? Do they exist only in the divine mind? Do the senses play any role in the process of concept formation? Later medieval philosophers would handle these issues in interestingly different ways.

Thirteenth-century Franciscans

Augustine's position would remain ascendent among Christian philosophers for most of the Middle Ages. Thirteenth-century Franciscans, led by figures such as Bonaventure (c.1217-1274) and Matthew of Aquasparta (c.1237-1302), gave the theory a detailed and systematic defense, focusing on the changeability and hence uncertainty of the human mind and the sensory world (see Rohmer 1928). Bonaventure characterically argues,

> Things have existence in the mind, in their own nature (*proprio genere*), and in the eternal art. So the truth of things as they are in the mind or in their own nature -- given that both

> are changeable -- is sufficient for the soul to have certain knowledge only if the soul somehow reaches things as they are in the eternal art (*De scientia Christi*, q.4 resp.).

Certain knowledge requires steadfast unchangeability. Since that can be found only in the divine mind, and since we have access to the divine mind only through illumination, certain knowledge requires illumination.

This line of argument came to seem increasingly old-fashioned as the thirteenth century progressed. The growing influence of Aristotle's theory of cognition, as developed in particular by the Dominican friars Albert the Great (c.1200-1280) and his student, Thomas Aquinas (c.1225-1274), offered an impressive picture of how human beings might be able to achieve certain knowledge despite the changeability of mind and matter. These developments struck many Franciscans as a betrayal of Christianity. John Peckham (c.1225-1292), in a letter dating from 1285, writes

> I do not in any way disapprove of philosophical studies, insofar as they serve theological mysteries, but I do disapprove of irreverent innovations in language, introduced within the last twenty years into the depths of theology against philosophical truth and to the detriment of the Fathers, whose positions are disdained and openly held in contempt.

Continuing, Peckham criticizes the doctrine

> which fills the entire world with wordy quarrels, weakening and destroying with all its strength what Augustine teaches concerning the eternal rules and the unchangeable light.... (quoted in Gilson 1955, p.359).

At roughly the same time, Roger Marston (c.1235-1303) writes of those who, "drunk on the nectar of philosophy... twisted toward their own sense all of Augustine's authoritative texts on the unchanging light and the eternal rules" (*Quaestiones disputatae de anima* 3 ad 30).

Marston's view is particularly interesting because he proposes a synthesis of Augustine and Aristotle. On his view,

> It is necessary to posit in our mind, beyond the phantasms or abstracted species, something by which we to some degree attain the unchanging truths. I believe this to be no different than the influence of the eternal light.... For the eternal light, irradiating the human mind, makes a certain active impression on it, from which a certain passive impression is left in it, which is the formal principle of cognizing the unchanging truths (*De anima* 3, p.263).

Rather than dismiss the agent intellect as superfluous, Marston follows Alexander of Aphrodisias et al. in treating the agent intellect as separate and divine -- indeed, as God himself. Earlier in the thirteenth century, William of Auvergne (c.1180-1249) had likewise identified the agent intellect with God (*Tractatus de anima* 7.6; cf. Gilson 1926-27, pp.67-72). Such cases illustrate how the various medieval

disputes over whether human beings might share a single intellect -- so absurd on their face -- are in fact simply alternative formulations of the dispute over divine illumination. But there were subtle differences among the various approaches. So whereas Auvergne largely turns his back on Aristotle, Marston is more accommodating. In addition to the divine agent intellect, he allows that each human being possesses its own agent intellect.

On Marston's account, Aristotle and Augustine turn out to be entirely in harmony: each uses his own terminology to defend the same theory of divine illumination (*De anima* 3, p.258). Étienne Gilson (1933) has characterized Marston's position as Augustinianism gone Avicennian (*Augustinisme avicennisant*). But this label unfairly prejudices the case in favor of Aquinas's perspective: it assumes that Marston has been seduced by an Islamic misreading of Aristotle, and it closes off the possibility that Augustine and Aristotle might have more in common than is typically allowed.

The case of Peter John Olivi (1247/8-1298) demonstrates how precarious a position the illumination theory held by the 1280s. Olivi, a Franciscan whose work would eventually be condemned by his own order, presents a compelling critique of the Augustinian illumination theory (*I Sent*., q.2), presenting his comments in the form of "cautions" (*cavenda*). The theory, he notes, is often very vague with respect to the actual process of illumination. And in running through the various possible accounts of the process available to a defender of the theory, Olivi appears to rule out every one. The eternal reasons cannot represent things distinctly and specifically, because then we would have no need of any sensory input. But if the eternal reasons give us information only of a general and indistinct sort, then at what level of generality? Does it supply us with information about species, or genera? If divine illumination is efficacious at any level, why do we seem to need the senses for all of our concepts? Olivi's questions and cautions go on and on. But after laying an entire minefield of this sort for anyone who would defend divine illumination -- at ad 6 he rejects the Augustinian argument set out above by Bonaventure -- he nevertheless comes to the surprising conclusion that he accepts the theory:

> These things, since I don't know how to analyze them fully, I set out only as cautions. For although the stated position is in itself venerable (*sollemnis*) and sensible, it could nevertheless be quite dangerous to those who are not carefully supervised. And so I hold the stated position as it is, because it belongs to men who are highly venerable. Nevertheless I leave an exposition of the above to their wisdom (q.2, pp.512-13).

This was a favorite strategy of Olivi's: to criticize a theory fiercely, exposing seemingly devastating difficulties, and then to embrace the theory anyway, as a pious gesture of respect. It's hard to resist reading between the lines, and concluding that dusk was fast approaching for the theory of divine illumination.

Thomas Aquinas

Thomas Aquinas is often thought of as the figure most responsible for putting an end to the theory of divine illumination. Although there is some truth to this view, as we will see, it seems more accurate to

regard Aquinas as one of the last defenders of the theory, as a proponent of innate Aristotelian illumination.

A vivid example of the way Aquinas moves from an Augustinian to an Aristotelian framework occurs in his Treatise on Human Nature (*Summa theologiae* 1a 75-89), where he considers the Augustinian claim that "pure truth should not be looked for from the senses of the body" (84.6 obj.1). In reply, Aquinas invokes the Aristotelian agent intellect:

> From those words of Augustine we are given to understand that truth is not *entirely* to be looked for from the senses. For we require the light of agent intellect, through which we unchangeably cognize the truth in changeable things, and we distinguish the things themselves from the likenesses of things (ad 1).

It is not at all clear, here or elsewhere, how the agent intellect carries out the two tasks he describes. (If Aquinas had given us a satisfactory account of this, he would have thereby solved the leading problems of epistemology.) But for present purposes it is enough to notice how Aquinas seems to replace Augustinian illumination with the Aristotelian agent intellect. Thus the traditional verdict has been that Aquinas replaced Augustine with Aristotle, and exchanged illumination for abstraction.

There is more to the story. In the immediately preceding article, Aquinas explicitly discusses Augustinian divine illumination, and reaches the affirmative conclusion that "the intellective soul does cognize all true things in the eternal reasons" (84.5sc). Often this affirmative conclusion gets treated as little more than lip-service to the authority of Augustine, and the article as a whole gets taken as a backhanded repudiation of illumination theory: affirming the theory in form but denying it in substance. This is a misreading. Aquinas sees something important in Augustine's theory, something worth preserving.

Aquinas does reject certain conceptions of divine illumination. He denies that human beings in this life have the divine ideas as an *object* of cognition. And he denies that divine illumination is sufficient on its own, without the senses. Neither of these claims was controversial. What Aquinas further denies, and what was controversial, was the claim that there is a special ongoing divine influence, constantly required for the intellect's operation. Aquinas instead argues that human beings possess a sufficient capacity for thought on their own, without the need for any "new illumination added onto their natural illumination" (*Summa theol*. 1a2ae 109.1c). From one perspective this makes for an important difference between Aquinas and his Franciscan contemporaries. But from another perspective the difference seems slight, because Aquinas is by no means removing God from the picture. Here is how he expresses his endorsement of illumination theory:

> It is necessary to say that the human soul cognizes all things in the eternal reasons, through participating in which we cognize all things. For the intellectual light that is in us is nothing other than a certain likeness of the uncreated light, obtained through participation, in which the eternal reasons are contained. Thus it is said in Psalm 4, *Many say, Who shows us good things?* To this question the Psalmist replies, saying *The light of your face,*

> *Lord, is imprinted upon us*. This is as if to say, through that seal of the divine light on us, all things are demonstrated to us (*Summa theol*. 1a 84.5c).

There is some temptation to take all of this simply as an expression of Aquinas's more general view that God is the first cause of all things. He writes, for instance,

> *All* active created powers operate in virtue of being directed and moved by the Creator. So it is, then, that in all cognition of the truth, the human mind needs the divine operation. But in the case of things cognized naturally it does not need any new light, but only divine movement and direction (*In de trinitate* pro. 1.1c).

Here there seems to be nothing special about the intellect's need for illumination. The intellect, like all of nature, needs God as its first mover. If you like, think of this as divine illumination. But viewed under this aspect, it is no wonder the theory was controversial. While his Franciscan contemporaries were insisting on a special role for God in human cognition, Aquinas seems to move as far in the opposite direction as his theism would permit.

But passages of this last kind are misleading, because Aquinas does see something especially mysterious about human cognition, and he appeals to God as a way of solving this mystery. The agent intellect, on Aquinas's view, accounts for our capacity to grasp self-evident truths. We have an immediate and direct grasp of the truth of first principles, such as the principle of noncontradiction (see, e.g., *Summa contra Gentiles* II.83.1678). We do not infer the truth of this principle, we do not discover that it is true through any kind of induction. Instead we simply see its truth, as soon as we are confronted with an instance where it applies. This is not innate knowledge; we are not born knowing these principles. What we are born with is the capacity to recognize their truth as soon as we are confronted with instances of them. These first natural conceptions are "the seeds of all the things that are subsequently cognized" (*De veritate* 11.1 ad 5). In this sense, Aquinas is even willing to speak of the soul's having a prior knowledge of everything that it knows:

> The soul forms in itself likenesses of things inasmuch as, through the light of agent intellect, forms abstracted from sensible objects are made actually intelligible, so as to be received in the possible intellect. *And so, in a way, all knowledge is imparted to us at the start*, in the light of agent intellect, mediated by the universal concepts that are cognized at once by the light of agent intellect. Through these concepts, as through universal principles, we make judgments about other things, and in these universal concepts we have a prior cognition of those others. In this connection there is truth in the view that the things we learn, we already had knowledge of (*De veritate* 10.6c).

Because all of what we know can be traced back to these fundamental principles, there is a sense in which everything we learn, we already knew. An innate grasp of certain basic truths, recognized by the light of agent intellect, plays a crucial, foundational role.

The light of agent intellect is of course given to us from God -- "a certain likeness of the uncreated light, obtained through participation" (1a 84.5c). Without appealing to God, Aquinas sees no way of explaining how we recognize the truth of first principles. Neither deductive nor inductive reasoning can account for the way in which we immediately *see* that such principles are true. This insight, then, is simply something we are given:

> The light of this kind of reason, by which principles of this kind are known to us, is imparted to us from God. It is like a likeness of the uncreated truth reflecting in us. So, since no human teaching can be effective except in virtue of that light, it is clear that it is God alone who internally and principally teaches us (*De veritate* 11.1c).

The light of agent intellect, a likeness of the divine ideas, is the essential starting-point for all knowledge. This is the epistemological context for Aquinas's famous words, *Non nisi te*.

Aquinas agrees with his Franciscan contemporaries that intellective cognition is incomplete without some sort of supernaturally infused insight. The only difference is that Aquinas wants that insight to be given all at once, from the start -- bottled up within agent intellect, as we might think of it. His opponents, in contrast, think of illumination as an ongoing process, as necessary as the air we breathe. It is easy to see how, at the time, this difference might have seemed important. But from our present perspective the differences seem rather slight: they seem to be arguing simply over the means of transmission. Aquinas conceives of illumination as a deep well within us, whereas the Franciscans conceived of it as raining down in drops.

Henry of Ghent

Although in a sense Thomas Aquinas defends a version of divine illumination, he in another sense clearly weakens the theory by giving it the status of an innate gift rather than ongoing patronage. In making for the agent intellect a central place in his theory of cognition, Aquinas has less room for illumination. As the thirteenth century progressed, philosophers and theologians were increasingly willing to make this tradeoff. While the Aristotelian theory of cognition waxed, the Augustinian theory of divine illumination waned. To combine the two seemed, in the words of Étienne Gilson (1930), "unproductive and even, in a sense, contradictory."

It is this seemingly contradictory task that Henry of Ghent (c.1217-1293) took upon himself in the years immediately after Aquinas's death. Ghent was neither Dominican nor Franciscan, but a so-called "secular" master at the University of Paris. His project was to defend an Aristotelian theory of cognition while at the same time reviving divine illumination in its traditional Augustinian form. To those, like Aquinas, who were arguing for the self-sufficiency of the human cognitive powers, Ghent replies,

> this is true for natural things, as regards knowing what is true of the thing.... Pure truth, however, or any truth that must be cognized supernaturally, or perhaps any truth at all,

> cannot be known without God himself doing the teaching (*Summa* 1.7 ad 1; 17rM).

On Ghent's terminology, to know what is *true* of a thing is simply to have a veridical impression of it: to represent a thing as it is. To grasp the *truth* of a thing, in contrast, is to grasp its nature. Only this latter sort of cognition counts as knowledge in the strict sense, because only here are we getting at the unchanging reality of the material world.

> For there is no knowledge of things insofar as they are external in effect, but insofar as their nature and quiddity is grasped by the mind (*Summa* 2.2 ad 1; 24rG).

For knowledge of this kind, divine illumination is necessary.

Ghent's argument is interestingly different from that of Augustine and his Franciscan followers. Whereas they had dismissed the physical world as too changeable to be a fit subject for human knowledge, Ghent believes that pure truth and certain knowledge can be had of the physical world, provided we manage to grasp the real essences of things. Since we cannot do so on our own, we need divine illumination to go beyond sensory appearances, to have genuine insight into the nature of reality. At its most basic level, Ghent is offering a critique of the agent intellect. Although he accepts the doctrine of agent intellect, he refuses to give that faculty the kind of efficacy that it has for Aquinas and other medieval Aristotelians. Not surprisingly, Ghent proposes reviving the earlier thirteenth-century tradition of referring to God himself as a kind of agent intellect (*Quodlibet* 9.15). But Ghent is no longer proposing to synthesize Augustine and Aristotle; he wants to supplement Aristotle's incomplete account with the necessary Augustinian illumination. (This is a summary of the account in Pasnau 1995.)

John Duns Scotus

It was the Franciscan John Duns Scotus, more than anyone else, who put an end to the theory of divine illumination. (John Boler remarks [in correspondence] that "as with Nixon's trip to China, it probably could only be done by a Franciscan.") Scotus criticizes Ghent's argument in detail (*Ordinatio* I.3.1.4), arguing against Ghent's own arguments, against the skeptical consequences that would allegedly come from giving up divine illumination, and against the viability of such illumination in its own right. With respect to the last point, Scotus argues that if human cognition were fallible in the way Ghent argues, then outside illumination could not, even in principle, ensure "certain and pure knowledge." On Ghent's account, the human mind cooperates with the divine light in achieving such knowledge. Scotus replies:

> When one of what comes together is incompatible with certainty, then certainty cannot be achieved. For just as from one premise that is necessary and one that is contingent nothing follows but a contingent conclusion, so from something certain and something uncertain, coming together in some cognition, no cognition that is certain follows (*Ordinatio* I.3.1.4 n.221).

If one part of a system is fallible, then that fallibility infects the process of a whole. Scotus's startling claim is that if the human mind were intrinsically incapable of achieving certain knowledge, then not even divine illumination could save it.

Scotus's own view is that the human mind is capable of such knowledge on its own. If by "certain and pure truth" Ghent means "infallible truth, without doubt and deception," then Scotus thinks he has established that human beings "can achieve this, by purely natural means" (*Ord*. I.3.1.4 n.258). How *can* such a thing be established? How can the skeptic be refuted, without appealing to divine illumination? Scotus distinguishes four kinds of knowledge:

- self-evident (*principia per se nota*)
- inductive (*cognita per experientiam*)
- introspective (*cognoscibilia de actibus nostris*)
- sensory (*ea quae subsunt actibus sensus*)

The general strategy is to show that sensory knowledge rests on inductive knowledge, that inductive knowledge rests on self-evident knowledge, and that introspective knowledge can be defended as analogous to self-evident knowledge. Scotus's implicit aim is to shift as much weight as possible onto the broad shoulders of self-evident knowledge.

For Scotus, the self-evident is the bedrock on which other sorts of knowledge rest, and so he doesn't attempt to locate some further set of even more basic truths. Instead, he argues that our self-evident knowledge is foolproof because of certain psychological facts. When one considers a proposition like *Every whole is greater than its part*, one immediately grasps that the terms are related in such a way that the proposition must be true:

> There can be in the intellect no apprehension of the terms or composition of those terms without the conformity of that composition to the terms emerging (*quin stet conformitas*), just as two white things cannot arise without their likeness emerging (*Ord*. I.3.1.4 n.230).

When we see two white objects we immediately grasp, "without doubt and deception," their similarity to one another. Likewise, when we grasp a self-evident truth in our mind, we immediately grasp its truth. Of course, we won't grasp the truth of the proposition if we don't understand the meaning of the terms, but in that case we won't have truly formed the proposition in our mind. And in contrast to the analogous case of recognizing similarity, there is no room for sensory error here. The senses help us acquire certain concepts, but once we have those concepts, the senses drop out of the picture -- sensory reliability becomes irrelevant. Scotus offers the example of a blind man miraculously shown in his dreams an image of black and white. Once he acquires these concepts, he can recognize as truly and infallibly as anyone -- his blindness notwithstanding -- that white is not black (*Ord*. I.3.1.4 n.234).

Scotus is unwilling to discard Augustinian illumination entirely, and so he articulates four senses in which the human intellect sees infallible truths in the divine light. In each sense, the divine light acts not

on us but on the objects of our understanding. By giving objects their intelligibility (*esse intelligibile*), the divine intellect "is that in virtue of which secondarily the objects produced move the intellect in actuality" (*Ord*. I.3.1.4 n.267). When the human mind grasps a self-evident truth, it does so immediately and infallibly not because the mind has received any special illumination, but because the terms of the proposition are themselves intelligible: our grasp of a proposition "seems to follow necessarily from the character of the terms, which character they derive from the divine intellect's causing those terms to have intelligible being naturally" (*Ord*. I.3.1.4 n.268). It is not that we are illuminated by the divine light, but that the truth we grasp is illuminated.

This marks a turning-point in the history of philosophy, the first great victory for naturalism as a research strategy in cognitive theory. On Scotus's account, when we grasp some conceptual truth, nothing miraculous or divine happens within us: "the terms, once apprehended and put together, are naturally suited (*sunt nati naturaliter*) to cause an awareness of the composition's conformity with its terms" (*Ord*. I.3.1.4 n.269). It is of course God that gives the world its intelligibility, just as it is God that creates our cognitive powers. But what's new in Scotus is the idea that the mind is not a special case. From this point forward, divine illumination would cease to be a serious philosophical possibility.

Epilogue

It is easy to miss the significance of what Scotus brought about: in part because it now seems so inevitable, in part because Scotus comes at the end of a gradual trend toward naturalism, and in part because it's generally supposed that nothing of much philosophical importance happened between Aristotle and Descartes. Yet if one looks at the big picture of our evolving philosophical/scientific understanding of the mind, then it is clear that something important happened at the end of the thirteenth century.

Still, Scotus's impact shouldn't be overstated. Although divine illumination, so called, would no longer have prominent supporters, the tendency toward supernatural explanations of cognitive phenomena would survive well beyond the Renaissance. Descartes, to take just one prominent example, can speak of "certain seeds of truth which are naturally in our souls" (*Discourse on Method* 6, AT 64), and of "ideas implanted in the intellect by nature" (*Principles of Philosophy* 2.3, AT 42). In its details, the view is striking similar to Aquinas's: Descartes identifies these ideas as the basis of our knowledge of first principles; he holds that the ideas themselves are formed only in virtue of sensory impressions; he identifies God as the source of these ideas. Innate ideas are the modern successor to divine illumination. But by the seventeenth century the philosophical context has changed so dramatically that this must be regarded as a different topic.

Peter John Olivi

Peter John Olivi must be considered one of the most original and interesting philosophers of the later Middle Ages. Although not as clear and systematic as Thomas Aquinas, and not as brilliantly analytical as John Duns Scotus, Olivi's ideas are equally original and provocative, and scarcely known even to specialists in medieval philosophy.

1. Life and Work

Olivi (1248 - 1298) was born in Sérignan, in the Languedoc region of southern France. He entered the Franciscan order as a youth, studied in Paris without becoming a master of theology, and spent his life teaching at various Franciscan houses of study in southern France. (For biographical details, see Burr 1976, 1989.) Olivi's outspoken originality led him into conflict with religious authorities: his writings were condemned and burned twice, and this obviously limited the influence he would have on posterity. Although his philosophical views were controversial, what drew the most attention was his attacks on Church authorities. As an early leader of the so-called "Spiritual" reform movement within the Franciscan order, Olivi attracted both fervent followers and implacable enemies (see Burr 1989, 1993; Douie 1932).

Olivi produced a large and wide-ranging body of work, most of which has survived. Almost all of his philosophical views are contained in his (as yet untranslated) question-commentary on the second book of Peter Lombard's *Sentences*. This lengthy, carefully composed treatise takes up a wide range of

philosophical problems, such as the nature of matter, form, substance, quantity, the soul, causation, motion, and the problems of universals and individuation. In this article I will focus on just a few of Olivi's interesting philosophical views, summarizing material I have published elsewhere (see Pasnau 1993, 1997a, 1997b, 1999).

2. Human Freedom

Olivi devotes several extended questions to the topic of human freedom, beginning with the question of whether human beings even have free will (*liberum arbitrium*). Olivi's own argument for the affirmative begins by listing seven pairs of attitudes (*affectus*), each of which testifies to the existence of free will (Q57, p. 317):

1. Zeal and mercy
2. Friendship and hostility
3. Shame and glory
4. Gratitude and ingratitude
5. Subjugation and domination
6. Hope and distrust
7. Providence and negligence

Each of these attitudes, Olivi claims, is intelligible only given the existence of free will. More specifically, they are "its distinctive products, or its distinctive acts and habits" (ibid.). As he runs through the list, explaining how each attitude entails free will, it becomes clear that many of these claims are familiar ones. Zeal, for instance, is an angry reaction to bad deeds, motivated "only against the bad that one judges to have been done voluntarily, and thus which could have been freely avoided" (p. 318). Without free will, this attitude is based on an assumption that is "thoroughly false and grounded on a thoroughly false object" (p. 317). As zeal goes, so do the related phonemona of accusations, excuses, blame, and guilt. Generally, "a human being could no more be accused of some vice than he could be accused of death, for he could avoid the one as little as the other" (p. 336). Providence and negligence, the last pair on the list, likewise become meaningless : "For it is foolish to be careful about things that will occur necessarily" (p. 323). It becomes pointless to be careful about deliberation, for instance, "because the deliberation itself will or will not happen necessarily, and even one's carefulness will or will not occur necessarily" (p. 323).

For Olivi, these and other data stand as unshakeable evidence for the existence and nature of free will. He makes this clear from the beginning of his reply, when he introduces two premisses that "no one of sane mind ought to doubt" (p. 317). First, it is "impossible" for all of the attitudes of one's rational nature to be "thoroughly false and perverse and grounded on a thoroughly false and perverse object." Since Olivi thinks that the attitudes that distinguish us as rational creatures are founded on free will, giving up on free will would be to abandon most of what makes us human. We would become, he later says, "intellectual beasts" (p. 338). Second, it is impossible for attitudes to be entirely illusory when human beings improve and perfect themselves by assuming those attitudes (p. 317). If the practices of zeal,

deliberation, friendship, love, etc. were all founded on a false assumption, then surely these practices would not be so crucial to human well-being. Thus "no one of sane mind will believe that something could be the truth which so sharply puts an end to all good things and brings on so many bad things" (p. 338). In the face of these implications, we should reject whatever stands in the way of free will, whether that be the authority of Aristotle or some abstruse principle of metaphyics. "Even if there were no other argument establishing that [the denial of free will] is false, this alone ought to be sufficiently persuasive" (p. 338). Moreover, as he explicitly notes, we should be persuaded not just of our own free will, but of the free will of all human beings, since these arguments are based not on private experience, but on our relationships with others.

This top-down approach, beginning with the ethical and experiential data, leads Olivi to some provocative conclusions about the nature of will. He does not merely conclude that the will's choices are not necessitated; the further conclusion Olivi reaches is that the will, until it makes a choice, is entirely undetermined one way or another, and that it determines itself in the direction it chooses. This is something "every human being senses with complete certainty within himself" (p. 327). In arguing that the will determines itself, he means that it is a first mover, in need of no efficient cause other than itself. "Its free power is the cause of its motion, when it is moved, and the cause of its rest, when it rests" (ad 5, pp. 341-42). If the will did not have this capacity for self movement, then the will would have to be determined by something else, hence it would not be making its own choices. But this violates the unshakeable assumptions from which Olivi begins, because it would then turn out that the will is not autonomous, not making its own choices, hence not a suitable object of one's zeal or friendship, among other things.

Olivi is well aware that the lack of autonomy does not entirely preclude a sort of pseudo-zeal or pseudo-friendship. One might be angry with someone, for instance, not out of the conviction that the bad action was that person's fault, but simply in an effort to change that person's ways. But this line of thought does violence to our conceptions of ourselves and our fellow human beings. We want people to do the right thing not because they have been effectively manipulated, but "solely and purely because of the love of justice" (ad 22, p. 368). Further, when we urge a person to do the right thing, "we do not intend simply to move someone toward what is good, but rather to make it that he voluntarily moves himself toward the good" (p. 369).

Olivi's view obviously belongs within the libertarian camp in the free will debate. Indeed, it is arguable that Olivi deserves credit as the founder of this view. Although John Duns Scotus is better known as an early proponent of libertarian freedom, Scotus's views seem heavily indebted to Olivi (see Dumont 1995). An English translation of Olivi's writings on human freedom would be of enormous value.

3. Soul and Body

With the rediscovery of Arisotle's metaphysical and ethical works, thirteenth-century theologians devoted an increasing portion of their time to interpreting and developing Aristotelian accounts of human nature. Olivi was very far from a slavish admirer of Aristotle's -- indeed, he was if anything rather hostile to the

Philosopher's pervasive influence, once remarking that "without reason he is believed, as the god of this age" (Q58 ad 14, p. 482; see Burr 1971). This hostility manifests itself in many ways, one of the most notable being his attempt to rework Aristotle's account of the soul-body relationship.

Olivi questions a central strand of the Aristotelian account, arguing that it is "not only contrary to reason but also dangerous to the faith" to hold that "the [soul's] intellective and free part is the form of the body per se and considered as such" (Q51; p. 104). Others had questioned the extent to which soul and body could be analyzed in terms of form and matter. But Olivi goes farther because he explicitly denies that one part of the soul, the rational part, can be understood as the form of the body. As a consequence, he was condemned by the Council of Vienne in 1312. Pope Clement V, in the bull *Fidei catholicae fundamento,* declared it a heresy to hold that "the rational or intellective soul is not per se and essentially the form of the human body" (Denzinger 1965, n. 902).

Olivi denies that "the [soul's] intellective and free part is the form of the body per se and considered as such" (Q51; p. 104). This matches fairly closely with the doctrine that was condemned. But it is easy to misunderstand what Olivi is saying. First, he is not denying that the rational part of the soul is a form, or even that it is the form of a human being. He in fact believes that the rational part, intellect and will, is the form of a human being's spiritual matter, and for that reason he thinks it acceptable to speak of intellect as the form of a human being (see Q51 appendix, p. 146). But he contrasts spiritual matter with corporeal matter, and as a result he denies that the rational part is the form of the body.

Second, Olivi is not denying that the soul is the form of the body. What he denies is that the rational part of the soul ("the intellective and free part") is the form of the body. Another part of the soul, the sensory part, is the form of the body, and for that reason it is acceptable to say that the whole soul is the form of the body:

> It is said that the whole rational soul, rather than the sensory part, is the form of the body, even though it is informed by the whole only insofar as it is informed by the soul's sensory and nutritive part (Q51 app., p. 146).

We should say that the whole soul is the form of the body, in much the same way that we say a person talks, not a tongue (p. 144). But if we direct our attention to the various parts of the soul, then it is wrong to say that the rational part, "per se and considered as such," is the form of the body. The soul is the form of the body only with respect to its sensory and nutritive part.

Despite his anti-Aristotelian invective, Olivi might plausibly be said to be agreeing with Aristotle, who explicitly leaves room for parts of the soul that "are the actuality of no body" (*De an.* II 1, 413a7). Presumably, Aristotle is thinking of the intellect. But it's not at all obvious how that remark should be interpreted. Aquinas, for instance, holds without qualification that "the intellect... is the form of the human body" (*Summa theologiae* 1a 76.1c). So what is it that compels Olivi to drop intellect from the hylomorphic scheme?

Olivi writes that to identify the rational part -- "per se and considered as such" -- as the form of the body is "not only contrary to reason but also dangerous to the faith" (as above). More specifically, as he writes in a letter defending his views, he believes that that claim holds "the danger of destroying the soul's immortality, its liberty, and its intellectual nature" (*Epistola* n. 7). Each of these three consequences is based on one overarching assumption: that to make the soul's rational part the form of the body is to attribute to the body the distinctive capacities of the rational soul. Here is how Olivi puts that claim:

> If the intellective part is the form of the body then, since all matter is actualized by its form, it follows that just as a human body is truly sensory and living through the sensory soul, so that body will be truly intellective and free through the intellective part (Q51; pp. 104-5).

If the intellect is the form of the body, then the body must have the capacities for intellectual thought and free decision. Olivi is of course going to reject that as absurd. Notice the form of this argument. First, Olivi asserts that to be the form of something is to impart actuality to that thing. This seems uncontroversial. Second, Olivi argues by analogy. Just as the sensory soul actualizes a body by giving it life and the capacity for sensation, so the intellective part -- if it is the form of the body -- should actualize the body by making it intellective and free. Here too, I think, Olivi's claim seems plausible. If one accepts the first step of the argument, that to be the form of something is to impart actuality to that thing, then the rational part must be giving *something* to the body. Olivi says, "every form imparts to its matter some operation, and some power for operating" (Q51; p. 109). So, if the rational part does not give the body the capacity for intellective thought, we have to provide some sort of account of what the rational part does give the body. But what else could the rational part of the soul do for the body, if not endow it with the power to be rational?

We might view this argument as posing a dilemma. If the rational part is the form of the body, then one must either understand this formal relationship in the ordinary way, in terms of actualizing the body, or one must concede that the rational part is not the form of the body in any ordinary sense. The first horn of the dilemma leads in the direction of materialism, because it forces one to claim that the powers of the rational soul are instantiated in the body. The second horn of the dilemma leads one toward retracting the original assertion: that the rational part, the intellect, is the form of the body. For it is not at all clear what that means, if intellect is not in any way actualizing the body.

4. Cognitive Activity and Attention

One of the most interesting and original aspects of Olivi's philosophy is his critique of the standard Aristotelian model of cognition. The starting point of this critique is his insistence that sensation and intellection are active, not passive. On the conventional medieval view, a cognitive power simply receives impressions from the world, in the form of sensible or intelligible species. Olivi argues that such an account leaves out a crucial element, the focusing of the cognitive power's attention on the object to be cognized.

> However much the cognitive power is informed through a disposition and a species differing from the cognitive action, it cannot advance to a cognitive action unless before this it actually tends toward the object, so that the attention of its intention should be actually turned and directed to the object (Q72, p. 9).

Olivi gives the kinds of examples that one would expect. The ears of someone sleeping, for instance, receive the same impressions as the ears of someone awake, but the sleeper does not sense these impressions. Even when we are awake, we sometimes don't perceive objects right in front of us when we are intently focused on something else (Q73, pp. 89-90).

Olivi argues that this kind of cognitive atttention requires a "virtual extension" toward the object. One striking consequence of this claim is that the object itself needn't exert any causal influence, not on the cognitive faculties nor even on the physical sense organs. The external object need only be close enough to be apprehended by the cognizer's spiritual attention. In the cases of both sensation and intellection, the efficient agent is the cognitive power. The external object is merely a kind of final cause or, more precisely, a "terminative cause." (Q72, p. 36; *Epistola*, n. 12). It is merely by being the object of the cognitive power's attention that the external object plays a role in cognition. Though Olivi accepts the traditional theory of *species in medio*, sensible qualities that fill the air between the senses and their objects, he denies that these species are the efficient cause of cognition.

Is a virtual extension, as Olivi describes it, some special (perhaps nonphysical) but perfectly real kind of extension or extromission to external objects? The bulk of the evidence seems to show that Olivi means ‘virtual’ and ‘virtually’ to contrast with ‘real.’ He explicitly denies, for instance, that this virtual extension involves "any real emission of its essence" (Q73, p. 61). Elsewhere, considering the claim that "our mind is where it fixes its intention," he says that "these words are metaphorical. For we are not there really or substantially, but only virtually or intentionally" (Q37 ad 13, p. 672).

Olivi treats virtual attention not as a sui generis activity of the mind, but as a general kind of causal relationship that can be applied to physical agents just as much as to mental ones. For Olivi, every natural physical agent has a virtual attention of this sort that extends as far as its causal force does (Q23, pp. 424-25). One authority comments that Olivi's virtual attention is "in fact equivalent to action at a distance" (Jansen 1921, p. 118), a characterization that seems just.

Olivi allows that the object itself, through *species in medio*, can indirectly act on our spiritual faculties, through what he calls the *via colligantiae* (way of connection). A flash of lightning will make a physical impression on our eyes, and this physical impression can, through the *via colligantiae*, affect the spiritual sensory powers. But, crucially, this connection is not what brings about sensation. We *see* this flash, as opposed to receiving merely a physical impression from it, when we direct our spiritual attention toward it (*Quodlibet* I.4). This *via colligantiae* plays an important role across Olivi's philosophy of mind and the will, being his general method of explaining the vexed connection between mind and body (see Q59, pp. 546-54, and Jansen 1921, pp. 76-90).

5. Direct Realism

Olivi's direct realism is central to his thinking about cognition. If he were willing to say that the object of our spiritual attention is not the external object but an internal species of the object, then he could reformulate his theory of cognitive attention in a more plausible way, as a matter of grasping an internal impression from the object. But Olivi works very hard to avoid falling into any kind of position that might be called representationalist -- that is, a view on which the immediate objects of cognition are internal. It is this direct realism, above all else, that leads Olivi to reject the standard scholastic account of sensible and intelligible species. On that standard account, species serve as forms that provide the intentional content of sensation and thought. Although these forms were standardly described as merely the means by which we grasp external things, Olivi argued that in fact the proponent of species was committed to representationalism.

Olivi argues against the species theory by advancing through a series of ever-more-serious charges. First, the theory is committed to taking species as the objects of cognition:

> A species will never actually represent an object to the cognitive power unless the power attends to the species in such a way that it turns and fixes its attention on the species. But that to which the power's attention is turned has the character of an object, and that to which it is first turned has the character of a first object. Therefore these species will have the character of an object more than the character of an intermediate or representative source (Q58 ad 14, p. 469; cf. Q74, p. 123).

His argument for this conclusion turns on the first sentence of the passage, in which he claims that a species could not represent an object to a cognizer unless the cognizer attends to the species. Olivi takes this attention to the object to be both a necessary and a sufficient condition for a cognition of that object. So if we do have to focus our attention in this way on species, he infers that those species will be the object of cognition, not merely causal intermediaries.

Next, Olivi argues that species would have to be the first object of cognition. To turn toward a species in the way that we must if that species is to represent the external world "is the same as to attend to it as a first object" (Q74, p. 123). Elsewhere, "we would always cognize the species before the thing itself that is the object" (Q58 ad 14, p. 469). The point Olivi wants to make is one more often made by denying that the world is seen *directly* or *immediately*. If we see the external world at all, we see it only at second hand, indirectly.

The argument goes one final step. Someone who wants to claim that our internal sensations are themselves perceived has to choose whether or not to claim that the external world is also perceived. Olivi takes it that it is not; on the species account, we would not perceive the external world at all, only images of it:

> The attention will tend toward the species either in such a way that it would not pass beyond so as to attend to the object, or in such a way that it would pass beyond. If in the first way, then the thing will not be seen in itself but only its image will be seen as if it were the thing itself (Q74, p. 123; cf. Q58 ad 14, pp. 469-70, 487-88).

The argument is based on a dilemma. Granting that cognizers must attend to species, there either will or will not be a separate and further attention to the object itself. It would of course be quite odd to say that there is such a further attention. This would entail, as Olivi goes on to say, that one "considers the object in two ways -- first through a species, second in itself" (Q74, p. 123). This seems too much at odds with the phenomenal feel of perception to be a serious possibility. The obvious way out of the dilemma, then, is to say that there will not be any further attention: one apprehends the external world, if one does at all, in virtue of attending to the species themselves. This is what the representationalist will likely say. But if this is the case, Olivi argues, then we won't be seeing the things in themselves but only their images. Memorably, he remarks that a species "would veil the thing and impede its being attended to in itself as if present, rather than aid in its being attended to" (Q58 ad 14, p. 469).

In place of the species theory, Olivi offers an interesting alternative. Rather than treat mental representations as something separate from an act of cognition, Olivi proposes identifying the two. On his view, an act of cognition is itself a representation of the object perceived. There is no need to postulate any further representation beyond the act itself: that inevitably results in the mediation that Olivi wants to avoid. This act theory would prove influential on later scholastics, most notably William Ockham. And in our own era it has been reinvented and renamed, as the adverbial theory of thought and perception.

6. Word and Concept

Olivi extends his critique of species to the mental word (*verbum*), which was standardly postulated as the product of intellectual thought. His treatment of the *verbum* raises different issues from those associated with species. Here the issue is not direct realism, precisely, but rather the nature of concept formation. Near the start of his commentary on the Gospel of John, Olivi describes the standard view as follows: "Our mental word is something following an act of thought... and formed by that thought.... After it has been formed... the [extra-mental] object is clearly understood or viewed in that word as if in a mirror" (*Tractatus de verbo* 6.1). This word, moreover, "is that which is first cognized by intellect and is its first object;" the extra-mental object is cognized secondarily. This description closely matches a characterization Olivi gives in his later *Sentences* commentary:

> Some maintain that a kind of concept, or word, is formed through an abstractive, investigative, or inventive consideration, in which real objects are intellectively cognized as in a mirror. For they call this the first thing understood, and the immediate object; it is a kind of intention, concept, and defining notion of things (Q74, pp. 120-21).

This view has two characteristic features. First, its postulates a mental representation -- a concept or word

-- that is the product of intellectual activity. Second, it supposes that we understand the world through these representations, in such a way that we get at the world indirectly, or secondarily, "as if in a mirror." Call this an object theory of the *verbum*.

Olivi's own view is that the *verbum* should be identified with a particular act of thought: "our mental word is our actual thought" (*Tractatus* 6.2.1). When we engage in abstract intellectual cognition, Olivi says, "nothing serving as an object is really abstracted or formed that differs from the act of consideration already mentioned" (6.2.3). The *Sentences* commentary offers a concise characterization:

> This [sort of intervening concept] ought not to be called a *verbum*, nor can [such a concept] be anything other than the act of consideration itself or a memory species formed through that act (Q74, p. 121).

There are, then, acts of intellect, but there are no separate inner concepts that are the objects of those acts. Call this an *act theory* of the *verbum*.

Why is this act theory superior to an object theory? One line of argument holds that the object theory "contains in itself obvious absurdities and thus contradicts sound reason" (*Tractatus* 6.2.2). This claim is argued in different ways, with the following dilemma often playing a crucial role: On one hand the *verbum* is said to be the product of intellectual cognition. But on the other hand the *verbum* is said to be required for cognition as the "first thing understood." How can it be both? Olivi thinks his opponents will have to maintain that in some way the *verbum* is the product of one act of intellect and the object of a second. This leads him to argue that his opponents are treating the *verbum* as merely a memory. But Olivi is happy to countenance representations of this sort. Thus the object theory collapses into the act theory.

The second line of attack holds that the theory lacks support because "there is no necessity or utility in postulating such a *verbum*" (6.2.3). Here Olivi considers two parallel lines of argument that a proponent of the mental word might make against this charge of superfluity.

> First,... we experience in ourselves that we form in our mind new concepts of many propositions and conclusions. These concepts remain in us later and we return to them when we want to remember such propositions.... Second,... from individuals seen or imagined by us we abstract and form defining characterizations of their universal features,... and we come back to these when we wish to view such universal features (6.2.3).

Each argument appeals to our experience of forming within ourselves abstract ideas: in the first case propositional ideas, in the second universals. Intellect in each case is said to form a *verbum*. Olivi replies that no such inner word is necessary. In each case we have an act of conceptual thought, but no object is formed in intellect over and above the act of thinking itself. Indeed, if anything, such an object "would be an impediment" (6.2.3) -- alluding to the epistemological difficulties discussed in the previous section.

By eliminating the representations that might intervene between intellect and external reality, Olivi gives us what we might be tempted to think of as a direct realist theory of intellectual cognition. Yet direct realism faces a serious problem at the intellectual level, a problem that Olivi's discussion fails to acknowledge. Direct realism is attractive as a theory of sensation because it seems clear what the objects of sensation are. But what are we directly in touch with when our intellect thinks abstractly or propositionally? One answer to this question is Platonism: universals and/or propositions have some kind of abstract mode of existence, independently of the human mind. Like almost all the scholastics, Olivi firmly rejects this kind of account (Q13). Another kind of answer, sometimes called conceptualism, treats universals and/or propositions as mental constructs. Defenders of the object theory can take this approach. They can hold that although there are no universals or propositions *in re*, there are universals and propositions *in mente*. The *verbum*, serving as universal or as proposition, will (in some cautiously described sense) be the object of thought.

Olivi's act theory would seem to rule out this kind of conceptualism. But what then will Olivi put in its place? He speaks of intellect's "attending to and considering the real character of a common or specific nature" (376-379), as if he has an unproblematic account of intellect's relationship to the outside world. Yet he says nothing to clarify the status of this relationship. He simply does not seem to have recognized the problem of abstract knowledge as a fundamental metaphysical motivation for the object theory. In this respect his overall account, although conceptually innovative, remains fundamentally incomplete.

Medieval Theories of Practical Reason

Medieval theories of moral reasoning have their origins in the moral theology of St. Augustine and the rational ethics of Aristotle. Until the thirteenth century Augustine's responses to questions concerning free will, predestination, the nature of goodness and divine freedom dominated moral speculation in the Latin West. For Augustine morality demands the human will's conformity to the prescriptions of the immutable, necessary and eternal law. Augustine argues in his work on free will that the eternal law "is called supreme reason, which must always be obeyed, and through it the evil deserve an unhappy life and the good a blessed life; and through this law we have derived temporal laws rightly constructed and correctly emended." The ideals of eternal law are universally imprinted upon human intellects and are the immutable standards by which human actions may be judged.

The Thomistic Doctrine of Practical Reason

When one chooses through one's free will to live ‘honorably and rightly’ in accordance with divine law, one can reasonably be thought to live a moral life. Despite the human ability to reason according to divine principles, the human condition does not permit the attainment of moral perfection through natural means alone. Augustine asserts that only through grace, sent freely by God to assist the human will can one achieve true moral goodness. Prudence, which is the ability to choose good and avoid evil, intellectual contemplation, moral and political virtue, friendship, education and character (all essential elements in Aristotle's ethics) are subsumed in Augustine's moral theology under the command to love God. For Augustine the complexity of Greek moral thought can be reduced to the simple rule of conformity to divine law.

Despite the contributions of Anselm in the eleventh century on questions concerning free choice, divine foreknowledge and predestination, and Peter Abelard's startling assertion in the twelfth century that morality arises from the agent's intention alone, it is not until the thirteenth century that a scientific

approach to human moral reasoning takes shape. Aristotle's Nicomachean Ethics, newly translated into Latin, provide a philosophical basis on which a fresh examination of Augustine's doctrines could be based. The first great medieval commentary on Aristotle's ethics, which was the result of Albert the Great's teaching activity at the Dominican House of Studies in Cologne, marks the beginning of 'moral science' in the Middle Ages. Albert's careful exposition of Aristotle's text and his clarification of the concepts of natural law, moral reasoning and human virtue, and its influence on his most famous pupil, Thomas Aquinas, led directly to a consideration of the question of practical reasoning in the Middle Ages.

The notion of medieval practical reason can be investigated in two ways: 1) in light of the distinction between practical and theoretical sciences in the writings of the medieval university masters in the thirteenth and fourteenth centuries; 2) in comparison to the modern understanding of practical reason as described by Immanuel Kant. The first method allows for a strict adherence to the texts themselves, wherein the concept of 'ratio practica' is strictly limited to a type of philosophical reasoning. The second approach permits a deeper philosophical consideration of the parallels between the medieval understanding of the nature of moral goodness and the modern view of the will as practical reason. Both approaches are helpful in gaining a fuller understanding of the meaning of practical reason in the Middle Ages.

In its strictest sense the term 'practical reason' (*ratio practica*) refers specifically to a type of reasoning, which is analogous to the deductions of speculative or theoretical science. When discussing human knowledge of the precepts of natural law Thomas Aquinas argues that these commands are related to practical reasoning as the first principles of demonstration are related to speculative reasoning; in each science there are certain principles of demonstration which are known in themselves (*principia per se nota*). These principles, which comprise the universal laws of moral behavior direct all subsequent moral reasoning. Thomas bases his theory of correct reasoning on the human ability to discover an underlying order in any field of inquiry. The order of reasoning which determines metaphysical knowledge is derived from a recognition of the principle of non-contradiction. Reasoning from the notion that being and non-being are contradictory terms, a metaphysician argues for certain conclusions about the nature of being. In practical reason one begins with the principle that all human acts are directed to an end and then comes to recognize the fundamental element of ethics to be 'do good and avoid evil':

> Therefore the first principle in practical reason is that which is based on the nature of the good which is: the good is that which all things seek. This therefore is the principle of law: that good must be done and evil avoided. And on this <precept> all other precepts of natural law are based so that everything which is to be done or avoided pertains to the precepts of natural law. Practical reason naturally understands these precepts to be human goods. (S. th. I-II, 94, 2).

Although Albert sees a closer connection between prudence and practical reason than Thomas ("prudence and practical reason have the same acts in that reason gives the act while prudence informs the act by reason of justice, expediency and honesty." De bono # 443), Albert essentially agrees with Thomas' description of the method of practical reasoning (Super Ethica, VI, 7, pp. 436-437).

Thomas argues from the basic principle that what is a good always has the nature of the end to the conclusion that human beings seek to discover particular good acts as consequences of the determined end. Since practical reason mimics the deductive process of theoretical reasoning, the term, '*ratio practica*', primarily refers to a type of human knowledge. There is, however, a fundamental difference between the conclusions of theoretical and practical science:

> Because speculative reason is especially concerned with what is necessary and cannot be otherwise, the truth found in its conclusions is without flaw, just <the truth> in its general principles. But practical reason concerns what is contingent whose domain is human acts; and so even if there is some necessity in its general <principles>, the more one descends to its proper conclusions the more one finds a defect <in truth>. In speculative reasoning the truth is the same for all, both in principles and in conclusions. In operative reasoning there is not the same truth or practical rectitude according to its proper <conclusions>, but only according to its common principles. (S. th. I-II, 94, 4; Super ethica, VI, 7, p. 441).

Since the goal of practical reason is action not knowledge, the truth attained by the intellect must be caused by its conformity to right desire. There can be no necessary science of practical reason, since virtuous activity allows for variety and derivation from the universal rule in particular instances. Moral matters, which are within the domain of practical reason, are varied and inadequate (*deformis*), and cannot therefore provide the certainty which is expected in theoretical reasoning. If we are to have any science of practical reason at all, we must be content to apply the principles to various conclusions and proceed from rough arguments which demonstrate truth in a general way.

The variety and differences among the will's acts lead Thomas Aquinas to use the term 'ratio practica' specifically to distinguish the method of moral reasoning from that of strictly scientific knowledge:

> Therefore one finds something in practical reason which is related to operations just as a proposition in speculative reason is related to conclusions. (S. th. I-II, 90, 1 ad 2).

Albert argues that despite the similarities in method between the two types of reasoning, the force of a practical conclusion depends more on a particular desire than a universal principle. Since human desires differ so greatly, moral arguments are merely general and imperfectly formulated. (Super ethica, VI, 16, p. 491). These distinctions which are derived from Aristotle's analysis of the nature of human knowledge, do not approach the understanding of science found in the philosophy of Kant. For Kant, speculation does not, and cannot, give us knowledge of being, nor should we begin with being as the object of science, as is seen in the medieval principle of existential non-contradiction. Kant restricts speculative science to a consideration of the laws of appearance. Practical science, or practical reason, in Kant's philosophy, however, is concerned with freedom rather the natural good or the human end. Kant's practical reason attains the kind of rigor, based on pure *a priori* principles, which would be impossible in the ethics of Aristotle, Albert and Thomas who are content with a science of practical reason whose domain is contingent and changeable acts. The secure foundation which Kant sought for every moral

choice would be considered beyond the scope of practical reason as formulated by the medieval commentators on Aristotle's ethics.

Despite their enthusiastic reception of Aristotle's works, the medieval moralists did not grant him complete authority in moral reasoning. The flexibility of Aristotle's ethics, which Thomas himself acknowledges, did not lead medieval writers to construct a moral theory which, like Aristotle's, is based on societal norms, tradition and human actions. The medieval moralists sought a more secure foundation for determining ethical action than Aristotle's appeal to the man of practical wisdom (*phronimos*). A modern author recognizes the tensions that exist in medieval ethical theory when he writes of Thomas Aquinas: ‘How is it that Aquinas can seem so Aristotelian in his description of human action and yet be so Augustinian in his insistence on the need for conformity to the eternal law?’ (Westberg, 34). The answer to this question lies the account of the genesis of the human moral act and the conditions for its rectitude. Practical reason requires a foundation more secure than the accepted practice of human actions. In the search for that basis, Thomas and his contemporaries construct a theory of practical reason far more complex than the mere designation of a type of intellectual reasoning; it becomes an account of the nature of moral goodness itself.

The designation of the will as rational appetite, its end as goodness and its relationship to the intellect are well-known features of medieval followers of Aristotle and need not be treated at length here. What is of more interest in a discussion of practical reason is the analysis of those first principles which regulate moral reasoning. Thomas in developing the ideas of his former teacher, Albert, insists that the will must be moved by an end that is perceived as good. (S. th. I-II, 6, 1 & 8, 1; Super ethica, VI, 7, pp. 436-437). More specifically he argues that:

> ... the good in common, which has the nature of the end, is the object of the will. Therefore because of this element the will moves the other powers of the soul to their acts. (S. th. I-II, 9, 1)

Even though the intellect moves the will by presenting the object to be desired, the will itself has a natural inclination toward the good. The ultimate human end, or supreme good, is beatitude, the perfect, all-encompassing human good. Such a supreme good could never be perceived by practical reason as evil. (S. th. I-II, 13, 6 & 10, 2 ad 3; Super ethica, VI, 17, p. 497). The determination of the human end as beatitude says very little about the first principles of practical reason upon which specific moral judgments should be based. When the will desires, it seems to want more specific objects than the vague longing for beatitude. Thomas and Albert specify their theory of volition by means of the doctrines of natural law, synderesis, and prudence.

The source of the first principles in any science is a critical element in determining the validity and nature of that science. In moral reasoning the origin of the principles of actions not only reveals the understanding of the nature of goodness, but directs also all subsequent analysis as well. In Thomas' theory of practical reason the first principle of human actions is that of law:

> Just as reason is the first principle of human acts, so too in this reason something is the principle with respect to every other act. Thus it is necessary for law to pertain principally and most extensively. The first principle in actions, for which there is practical reason, is the ultimate end. The ultimate end of human life is happiness or beatitude. It is necessary for law to reflect in the highest degree that order which leads to beatitude. (S.th. I-II, 90, 2)

Albert formulates this position succinctly when he says, "prudence is regulated by divine and human law." (Super ethica, VI, 4, p. 417). While no other law than the dictates of practical reason guides human choices, the eternal law (*lex aeterna*) primarily and principally orders a human being to the end and determines the corresponding means. As a result, acts that are at odds with the eternal law must always be considered as contrary to the dictates of practical reason. (S. th. I-II, 71, 6 ad 3).

The insistence upon the binding force of eternal law and the natural human inclination towards, and participation in, it (which is called natural law) marks a decisive step away from Aristotle's ethics of *phronesis*. The ground of moral action is no longer thought to be the conformity of conduct to that of an outstanding person (*phronimos*); it is found in an external and universally binding source (eternal law). The process of correct practical reasoning is governed, and measured, by the conformity of acts to the precepts of this law:

> A similar process is found in practical and speculative reason… just as in speculative reason conclusions of diverse sciences are produced from indemonstrable principles naturally known… so too from the precepts of natural law as if from certain common and indemonstrable principles human reason proceeds necessarily to those things to which it should be more particularly disposed. (S. th. I-II, 91, 3)

The recognition of the principles of natural law allows practical reason to demonstrate how a human being naturally participates in eternal law according to its common principles.

Developing ideas found in Albert's work, Thomas argues that the will must be determined by its acceptance of the dictates of practical reason, which necessarily conform to the precepts of natural law:

> that human reason rules the human will, by which its goodness is measured, comes from the eternal law, which is divine reason. Thus the goodness of the human will clearly depends much more on eternal law than on human reason, and where human reason is deficient it is necessary to turn to eternal reason. (S. th. I-II, 19,5; Super ethica, VI, 4, p.417)

The content of the precepts, the way they are known and their influence on volition are the final elements in the natural law theory of practical reason. The assertion that natural law reflects eternal law gives little indication as to its specific precepts, but it does indicate that according to the order of natural inclinations an order of the precepts of natural law exists. There is in a human being, as in all other types of being, a primary inclination to self-preservation. It is, however, in the discussions of synderesis that Thomas and

Albert most clearly identify those principles which are the foundation of human moral reasoning. Synderesis was introduced into Latin by Jerome, perhaps as a variant of the Greek term, '*syneidesis*' (insight), and has no meaning whatsoever in Greek. While Albert compares the moral principles of synderesis to the innate natural seeds of law (*seminaria iuris*), Thomas defines synderesis as "the law of our intellect insofar as it is a *habitus* containing the precepts of natural law which are the principles of human acts." (S.th. I-II, 94, 1, ad 2). In an earlier work Thomas explains synderesis either as a natural habit similar to the habit of principles, or as the power (*potentia*) of reason with such a habit. He sees little difference in these two designations, since each describes the universal natural ability of reason to recognize the first principles of morality. The parallels to speculative reasoning that marked practical reasoning are also a feature of deriving conclusions from the dictates of synderesis. Thomas' claim that the function of synderesis is to recognize universal moral laws leaves little doubt that he understood the first principles of practical reason, natural law and synderesis to be the same:

> Just as there is a certain natural habit of the soul whereby it knows the principles of speculative science, which we call the understanding of the principles, so too in the soul is there a certain natural habit of the first principles of actions, which are the natural principles of natural law; and this habit pertains to synderesis and exists in no other power than reason. (De veritate, q. 16, a. 1)

The specific dictate of synderesis which refers to the eternal law is that one must obey God; the primary imperative with respect to the natural law is that one should avoid evil and seek the good. These principles are obviously not mutually exclusive, 'but the dictate of reason to pursue good is rationally and necessarily derived from the command to obey God.' Synderesis is the ability of reason that never errs in the recognition of those universal rules of moral action, since a denial of their universal validity contravenes human reason. Reason can, however, err in the application of the universal principle to a particular action. Moral wrong is then the result of an imperfect, or false, deduction from the principle. So properly speaking, error is not ascribed to universal principles (synderesis), but rather to conscience which may incorrectly apply a universal judgment. (De veritate, q. 16, a. 2, ad 2; Super ethica VI, 7, p. 441).

The ability to apply correctly the principles of practical reason to specific acts in particular circumstances is the function of the intellectual virtue of prudence, defined succinctly as *recta ratio agibilium*. Prudence "represents the agent's ability to deliberate, decide and properly to order the process of practical reason to action." (Westberg, p. 187). Prudence does not, however, direct the will infallibly to right conclusions. Since it merely directs choices, but does not determine them, the will can be said to remain free. Thomas argues that the will can choose freely in three ways, although it could never express a desire contrary to the primary moral rule of pursuing good. The will can be mistaken 1) with respect to its own act in that it can either will or not will; 2) with respect to its object in that it can either want or not want a particular thing; 3) with respect to what is ordered to the end insofar as it wills a particular good or evil act. (De veritate, q. 16, a. 2, ad 2 & q. 16, a. 1). Thomas' description of the will's freedom seems at times to be overwhelmed by his insistence upon the will's determination by the human intellect. This theory of freedom seems to consist merely in the human tendency for faulty reason, since both Albert and Thomas think it unlikely, or even impossible, for a human being to choose contrary to knowledge of the first

principles and their application to particular circumstances:

> It should be said that the root of liberty is the will as subject, but reason as its cause. The will therefore can be freely drawn to diverse things, since reason can be drawn to diverse things, since reason can have various conceptions of the good. (S. th. I-II, 17, 1)

For Albert the delight that arises from intemperate desire does not corrupt the natural habit of prudence, but rather its rule, when prudence fails in drawing the proper moral conclusion. In other words, no one can act contrary to the universal principles of morality, but only in their particular application. (Super ethica, VI, 7, p. 441).

According to these views human freedom could never lead a human being to act contrary to his own interests. To choose against the principles of natural law would not constitute freedom, but rather foolishness. Although the will's natural inclination to pursue the good presented by the intellect does not compel the will to act, the moralists of the natural law theory think it psychologically impossible to choose something incompatible with a properly deduced conclusion of practical reason:

> A second necessity can be imposed on the will, namely the will must necessarily chose x, if x must be pursued as good or x is to be avoided as evil. (De veritate, q. 17, a. 3)

The Franciscan Critique

The ethics of natural law, with its impressive union of the Augustinian theory of eternal principles and the Aristotelian method of moral reasoning, did not remain long unchallenged. Franciscan theologians, John Duns Scotus and William of Ockham, were especially critical of a theory which they considered too restrictive of human freedom. Although Scotus and Ockham never produced treatises specifically devoted to moral theory, the main lines of their critiques may be sketched from their theological works.

Scotus' main concern in his arguments against the intellectualism of Albert's and Thomas' ethics is his doctrine of the supremacy and freedom of the human will. He claims that there could be no basis for judging an action right or wrong if the will were not free to choose against the dictates of the intellect. The will, even if it should act ‘with reason’ still is able to choose between opposite courses of action that lie within its power; the intellect however, has no power of self-determination, since it must assent to what it recognizes as true. Only the will acts freely, for it has the power of self-determination. Scotus argues that a theory of practical reason in which judgments about actions were restricted to the type of reasoning characteristic of speculation not only restricts freedom, but also removes any basis for merit or blame. If the moral agent must act in accordance with intellectual deduction, then he can only be praised for his intellectual prowess, and not for his moral goodness.

Scotus is influenced by Aristotle's assertion that the end of practical knowledge is truth in agreement with right desire. For Scotus this philosophical expression of the natural law leads him to assert one

fundamental universal moral principle: ‘God should be loved’. This law is so deeply rooted in human reason that even God's power cannot release a human being from its obligations. This principle allows Scotus to view his moral theology as consistent with Aristotle's ethics, since reason leads man to obey God's commands. The will necessarily and perpetually seeks happiness and the will naturally desires its own perfection. The primary universal command informs the will's natural desire for perfection, and so particular actions, regardless of circumstances, are judged in accordance with the will's conformity to the precept to love God.

Scotus' primary consideration as a moral theologian is the nature of freely determined volitional choices. Only secondarily does he consider the goodness of the desired end of the action. When the will freely chooses in accordance with right reason only then can the act be considered morally good. Scotus does have some difficulty explaining the relationship between the will and the intellect. If a human being realizes intellectually that the most desirable goal is union with God, it seems that human intellectual reason would compel him to pursue such an end. If the will does not act in agreement with the rationally derived first principle then it must be necessarily wrong. It is thereby difficult to see how the will's absolute freedom can be maintained.

Faced with such a dilemma, Scotus argues that although the will pursues an object rationally determined by the intellect, this does not mean that the will is conditioned by ‘natural necessity’. The apprehension of a possible action is offered to the will as something neutral, while the will remains always free. (Ordinatio, IV, d. 46). In Scotus' view the natural law is comprised of self-evident *a priori* principles, whose validity the intellect immediately recognizes from the coherence of terms. The will then is naturally inclined to assent to their dictates, but is not compelled to do so. For Scotus the clearest expression of natural law is the decalogue, which directs all human actions towards the attainment of beatitude. The commands of natural law are not good merely because they are commanded, but are commanded because they are good. (Ordinatio IV, 17) Scotus considers the first two commandments, that God must be worshipped and revered, to be absolutely unalterable. God himself could never negate such moral principles and human beings are morally bound to their adherence.

Despite his unrelenting criticisms of many of Scotus' positions, William of Ockham's moral theology develops, rather than dismisses, the main lines of Scotus' ethical deliberations. Ockham too is concerned primarily with the preservation of volitional freedom, both divine and human. Ockham specifically rejects the theory of natural law for determining human acts invariably toward an intellectually determined end. His insistence upon the dignity of human nature and the absolute power of the will for self-determination leads Ockham to reject his predecessors' morality of natural law. Ockham's critique of the metaphysics of common nature was not limited to logical and metaphysical speculation; it pertains also to his moral doctrine, wherein the will must be free even to choose ‘evil which is neither really or apparently good.’

The autonomy of the will is so great that it can absolutely refuse to pursue beatitude even when it is presented either as a general or particular idea. Even after death (*in patria*) the will can refuse to desire its own perfection. Volitional freedom is absolute in Ockham's moral theology; it can be defined as a natural inclination to an end, only insofar as it is an observed general human tendency. The human will

can just as easily reject its end, as it can pursue it. (Ordinatio I, d. 1, q. 6).

The natural foundation of morality, so essential to Albert and Thomas and still an important element of Scotus' thought, is rejected by Ockham in favor of a more complete notion of volitional freedom. Still Ockham does not advocate an ethics of relativism. The basis for human moral judgments lies in the will's conformity to divine commands. Impressed by Scotus' dictum, ‘Deus nullius est debitor’ (God is indebted to no one), Ockham extends the power of God to reformulate all moral laws. Not only can the commandments that regulate human interactions be altered, but also those that determine the relationship between God and man. God could command human beings to hate him and such a precept must be considered as morally binding. Ockham's use of the more common language of medieval moral theory does not prevent him from emphasizing the contingency of human morality. His belief in the power of human reason to discern the rational principles of an ordered life cannot overcome his desire to preserve the unlimited power of God, on whose will all moral principles depends and are subject to change. Both Scotus and Ockham construct a moral theory of volitional freedom, rather than one that they believe to be the moral determinism of Aristotle and his followers.

The final question remains: can the medieval explanations of practical reason be aligned with Kant's description of practical reason? Kant's well known definition of practical reason is:

> Everything in nature works according to laws. Only a rational being has the ability to act in accordance with the concept of laws, that is according to principles; in other words, only a rational being has a will. Since reason demands the derivation of actions from laws, the will is nothing other than practical reason. (Grundlegung zur Metaphysik der Sitten, II, 37)

For Kant the aim of moral philosophy is to discover ideas and principles that would constitute as pure a concept of will as possible and not to determine the actions and conditions of willing, which are mainly the concerns of psychology (Grundlegung, Intro., XII). The good will is good not through its result or its capacity to attain a predetermined end, but only by means of the willing itself. (Grundlegung, I, 3). The will's ability for self-determination according to universally binding laws conveys the objectivity demanded by the proper concept of reason. Since a rational nature declares itself by the self-imposition of the end, morality is the relationship of actions to the autonomy of the will; and this autonomy is the relation of the will to the most universal mandating (*Gesetzgebung*) possible. (Grundlegung, II, 83 & 85-86). The will purified of any inclination and desire for an ulterior end is the proper matter for practical reason.

The differences between Kantian and medieval theories of practical reason are obvious even from such a short description of their elements. The adherence of Albert and Thomas to the Greek view of human nature led them to their conviction of the will's natural inclination toward the good. Such a notion permits Thomas to advise us to seek naturally what is useful to us. (De veritate, q. 24, a. 8). What is truly advantageous to human beings must always be conducive to attaining the human end, beatitude; utility in this sense will always be a reliable guide to correct moral choice. Thomas claims that every thing to which man has a natural inclination human reason apprehends as good. For Kant human beings cannot be

permitted to pursue their inclinations which are to be viewed as subjective desires. Such desires lead to moral error at least as often as they produce right action. The objectivity of the pure concept of the human will precludes the recognition of human inclination as a measure of human goodness.

Despite their insistence upon volitional freedom, which in some aspects anticipates Kant's thought, Scotus and Ockham argue that the true measure of morality lies in the conformity of the human will with the commands of God. Such precepts may change if God so desires and so Scotus and Ockham produce an ethics quite different in spirit from that of Kant's theory of universal imperatives. Ockham in his rejection of the intellectual basis for morality argues that an act in total conformity with right reason may not be virtuous, since God could possibly create such an act without human volitional consent. The act would be completely rational and in conformity with divine commands, but would lack any merit or virtue. For Ockham the goodness of any action lies completely in the will's desire to obey divine commands (De connexione virtutum, III, 11). When Kant describes practical reason as a necessary law for all rational beings, whose actions are always to be judged according to maxims completely bound to the concept of the will of a rational being, one may see parallels to the Franciscan doctrine of the autonomy of the will. As Thomas and Albert describe the genesis of moral action as a process in which practical reason has the ability to accept, understand and obey the principles of a universal law consonant with human nature, they approach Kant's description of the dignity of the will more closely than those who insist upon the necessity for adherence to the possibly arbitrary precepts of God. Practical reason as the desire for the good as good, as expressed in the first principle of natural law or obedience to divine commands, and the conformity of the will through free choice to the universally binding principles of practical reason indicate that in some important elements of their moral theories medieval philosophers approach the spirit of Kant as they move away from the legacy of Aristotle.

Stanford Encyclopedia of Philosophy

Free Will

"Free Will" is largely a philosophical term of art for a particular sort of capacity of rational agents to choose a course of action from among various alternatives. Which sort is the free will sort is what all the fuss is about. (And what a fuss it has been: philosophers have debated this question for over two millenia, and just about every major philosopher has had something to say about it.) Most philosophers suppose that the concept of free will is very closely connected to the concept of moral responsibility. Acting with free will, on such views, is just to satisfy the metaphysical requirement on being responsible for one's action. (Clearly, there will also be epistemic conditions on responsibility as well, such as being aware -- or failing that, being culpably unaware -- of relevant alternatives to one's action and of the alternatives' moral significance.) But the significance of free will is not exhausted by its connection to moral responsibility. Free will also appears to be a condition on desert for one's accomplishments (why sustained effort and creative work are praiseworthy); on the autonomy and dignity of persons; and on the value we accord to love and friendship. (See Kane, 1996, 81ff.)

Philosophers who distinguish freedom of action and freedom of will do so because our success in carrying out our ends depends in part on factors wholly beyond our control. Furthermore, there are always external constraints on the range of options we can meaningfully try to undertake. As the presence or absence of these conditions and constraints are not (usually) our responsibility, it is plausible that the central loci of our responsibility are our choices, or "willings."

I have implied that free willings are but a subset of willings, at least as a conceptual matter. But not every philosopher accepts this. Rene Descartes, for example, identifies the faculty of will with freedom of choice, "the ability to do or not do something" (Meditation IV), and even goes so far as to declare that "the will is by its nature so free that it can never be constrained" (Passions of the Soul, I, art.41). In taking this strong polar position on the nature of will, Descartes is reflecting a tradition running through certain late Scholastics (most prominently, Suarez) back to John Duns Scotus.

The majority view, however, is that we can readily conceive willings that are not free. Indeed, much of the debate about free will centers around whether we human beings *have* it, yet virtually no one doubts that we will to do this and that. The main perceived threats to our freedom of will are various alleged determinisms: physical/causal; psychological; biological; theological. For each such variety of determinism, there are philosophers who (i) deny its reality, either because of the existence of free will or on independent grounds; (ii) accept its reality but argue for its compatibility with free will; (iii) accept its reality and deny its compatibility with free will. (See the entries on compatibilism; causal determinism; fatalism; and arguments for incompatibilism.) There are also a few who say the truth of any variety of

determinism is irrelevant because free will is simply impossible.

If there is such a thing as free will, it has many dimensions. In what follows, I will sketch the freedom-conferring characteristics that have attracted most of the attention. The reader is warned, however, that while many philosophers emphasize a single such characteristic, perhaps in response to the views of their immediate audience, it is probable that most would recognize the significance of many of the other features discussed here.

---

1. Rational Deliberation

1.1 Free Will as choosing on the basis of one’s desires

The minimalist account of free will is as the ability to select a course of action as a means of fulfilling some desire. David Hume, for example, defines liberty as "a power of acting or of not acting, according to the determination of the will." (1748, sect.viii, part 1). And we find in Edwards a similar account of free willings as those which proceed from one’s own desires.

One reason to deem this insufficient is that it is consistent with the goal-directed behavior of some animals whom we do not suppose to be morally responsible agents. Such animals lack not only an awareness of the moral implications of their actions but also any capacity to reflect on their alternatives and their long-term consequences. Indeed, it is plausible that they have little by way of a self-conception as an agent with a past and with projects and purposes for the future. (See Baker 2000 on the ‘first-person perspective.’)

1.2 Free Will as deliberative choosing on the basis of desires and values

A natural suggestion, then, is to modify the minimalist thesis by taking account of (what may be) distinctively human capacities and self-conception. And indeed, philosophers since Plato have commonly distinguished the ‘animal’ and ‘rational’ parts of our nature, with the latter implying a great deal more

psychological complexity. Our rational nature includes our ability to judge some ends as ‘good’ or worth pursuing and value them even though satisfying them may result in considerable unpleasantness for ourselves. (Note that such judgments need not be based in moral value.) We might say that we act with free will when we act upon our considered judgments/valuings about what is good for us, whether or not our doing so conflicts with an ‘animal’ desire. (See Watson 1982 for a subtle development of this sort of view.) But this would seem unduly restrictive, since we clearly hold many people responsible for actions proceeding from ‘animal’ desires that conflict with their own assessment of what would be best in the circumstances. More plausible is the suggestion that one acts with free will when one’s deliberation is *sensitive to* one’s own judgments concerning what is best in the circumstances, whether or not one acts upon such a judgment.

Here we are clearly in the neighborhood of the ‘rational appetite’ accounts of will one finds in the medieval Aristotelians. The most elaborate medieval treatment is Thomas Aquinas’s.[1] His account involves identifying several distinct varieties of willings. Here I note only a few of his basic claims. Aquinas thinks our nature determines us to will certain general ends ordered to the most general goal of goodness. These we will of necessity, not freely. Freedom enters the picture when we consider various means to these ends, none of which appear to us either as unqualifiedly good or as uniquely satisfying the end we wish to fulfill. There is, then, free choice of means to our ends, along with a more basic freedom not to consider something, thereby perhaps avoiding willing it unavoidably once we recognized its value. Free choice is an activity that involves both our intellectual and volitional capacities, as it consists in both judgment and active commitment. A thorny question for this view is whether will or intellect is the ultimate determinant of free choices. How we understand Aquinas on this point will go a long ways towards determining whether or not he is a sort of compatibilist about freedom and determinism. (See below. Good expositions of Aquinas’ account are Donagan, 1985, and Stump, 1997.)

There are two general worries about theories of free will that principally rely on the capacity to deliberate about possible actions in the light of one’s conception of the good. First, there are agents who deliberately choose to act as they do but who are motivated to do so by a compulsive, controlling sort of desire. (And there seems to be no principled bar to a compulsive desire’s being informing a considered judgment of the agent about what the good is for him.) Such agents are not willing freely. Secondly, we can imagine a person’s psychology being externally manipulated by another agent (via neurophysiological implant, say), such that the agent is caused to deliberate and come to desire strongly a particular action which he previously was not disposed to choose. The deliberative process could be perfectly normal, reflective, and rational, but seemingly not freely made. The agent’s freedom seems undermined or at least greatly diminished by such psychological tampering.

1.3 Self-mastery, rightly-ordered appetite

Some theorists are much impressed by cases of inner, psychological compulsion and define freedom of will in contrast to this phenomenon. For such thinkers, true freedom of the will involves liberation from the tyranny of base desires and acquisition of desires for the Good. Plato, for example, posits rational, spirited, and appetitive aspects to the soul and holds that willings issue from the higher, rational part

alone. In other cases, one is dominated by the irrational desires of the two lower parts.[2] This is particularly characteristic of those working in a theological context -- for example, the New Testament writer St. Paul, speaking of Christian freedom (Romans vi-viii; Galatians v), and those influenced by him on this point, such as Augustine. (The latter, in both early and later writings, allows for a freedom of will that is not ordered to the good, but maintains that it is of less value than the rightly-ordered freedom. See, for example, the discussion in Books II-III of *On Free Choice*.) More recently, Susan Wolf (1990) defends an asymmetry thesis concerning freedom and responsibility. On her view, an agent acts freely only if he had the ability to choose the True and the Good. For an agent who does so choose, the requisite ability is automatically implied. But those who reject the Good choose freely only if they could have acted differently. This is a further substantive condition on freedom, making freedom of will a more demanding condition in cases of bad choices.

In considering such rightly-ordered-appetites views of freedom, I again focus on abstract features common to all. It explicitly handles the inner-compulsion worry facing the simple deliberation-based accounts. The other, external manipulation problem could perhaps be handled through the addition of an historical requirement: agents will freely only if their willings are not in part explicable by episodes of external manipulation which bypass their critical and deliberative faculties. But another problem suggests itself: an agent who was a ‘natural saint’, always and effortlessly choosing the good with no contrary inclination, would not have freedom of will among his virtues. Doubtless we would greatly admire such a person, but would it be an admiration suffused with moral praise of the person or would it, rather, be restricted to the goodness of the person’s qualities? (Cf. Kant, 1788.) The appropriate response to such a person, it seems, is on an analogy with aesthetic appreciation of natural beauty, in contrast to the admiration of the person who chooses the good in the face of real temptation to act selfishly. Since this view of freedom of will as orientation to the good sometimes results from theological reflections, it is worth noting that other theologian-philosophers emphasize the importance for human beings of being *able* to reject divine love: love of God that is not freely given -- given in the face of a significant possibility of one’s having not done so -- would be a sham, all the more so since, were it inevitable, it would find its ultimate and complete explanation in God Himself.

2. Ownership

Harry Frankfurt (1982) presents an insightful and original way of thinking about free will. He suggests that a central difference between human and merely animal activity is our capacity to reflect on our desires and beliefs and form desires and judgments concerning them. I may want to eat a candy bar (first-order desire), but I also may want not to want this (second-order desire) because of the connection between habitual candy eating and poor health. This difference, he argued, provides the key to understanding both free action and free will. (These are quite different, in Frankfurt’s view, with free will being the more demanding notion. Moreover, moral responsibility for an action requires only that the agent acted freely, not that the action proceeded from a free will.)

On Frankfurt’s analysis, I *act* freely when the desire on which I act is one that I desire to be effective. This second-order desire is one with which I *identify*: it reflects my true self. (Compare the addict:

typically, the addict acts out of a desire which he does not want to act upon. His will is divided, and his actions proceed from desires with which he does not reflectively identify. Hence, he is not acting freely.) My *will* is free when I am *able* to make any of my first-order desires the one upon which I act. As it happens, I will to eat the candy bar, but I could have willed to refrain from doing so.

With Frankfurt's account of free will, much hangs on what being able to will otherwise comes to, and on this Frankfurt is officially neutral. (See the related discussion below on ability to do otherwise.) But as he connects moral responsibility only to his weaker notion of free action, it is fitting to consider its adequacy here. The central objection that commentators have raised is this: what's so special about higher-order willings or desires? (See in particular Watson 1982a.) Why suppose that they inevitably reflect my true self, as against first-order desires? Frankfurt is explicit that higher-order desires need not be rooted in a person's moral or even settled outlook (89, n.6). So it seems that, in some cases, a first-order desire may be much more reflective of my true self (more "internal to me," in Frankfurt's terminology) than a weak, faint desire to be the sort of person who wills differently.

In later writings, Frankfurt responds to this worry first by appealing to "decisions made without reservations" ("Identification and Externality" and "Identification and Wholeheartedness" in Frankfurt, 1988) and then by appealing to higher-order desires with which one is "satisfied," such that one has no inclination to make changes to them (1992). But the absence of an inclination to change the desire does not obviously amount to the condition of freedom-conferring identification. It seems that such a negative state of satisfaction can be one that I just find myself with, one that I *neither* approve nor disapprove (Pettit, 2001, 56).

Furthermore, we can again imagine external manipulation consistent with Frankfurt's account of freedom but inconsistent with freedom itself. Armed with the appropriate neurophysiology-tampering technology of the late 21st century, one might discreetly induce a second-order desire in me to be moved by a first-order desire -- a higher-order desire with which I am satisfied -- and then let me deliberate as normal. Clearly, this desire should be deemed "external" to me, and the action that flows from it unfree.

3. Causation and Control

Our survey of several themes in philosophical accounts of free will suggests that a -- perhaps *the* -- root issue is that of *control*. Clearly, our capacity for deliberation and the potential sophistication of some of our our practical reflections are important conditions on freedom of will. But any proposed analysis of free will must also ensure that the process it describes is one that was up to, or controlled by, the agent.

Fantastic scenarios of external manipulation and less fantastic cases of hypnosis are not the only, or even primary, ones to give philosophers pause. It is consistent with my deliberating and choosing 'in the normal way' that my developing psychology and choices over time are part of an ineluctable system of causes necessitating effects. It might be, that is, that underlying the phenomena of purpose and will in human persons is an all-encompassing, mechanistic world-system of 'blind' cause and effect. Many accounts of free will are constructed against the backdrop possibility (whether accepted as actual or not)

that each stage of the world is determined by what preceded it by impersonal natural law. As always, there are optimists and pessimists.

3.1 Free Will as guidance control

John Martin Fischer (1994) distinguishes two sorts of control over one's actions: guidance and regulative. A person exerts guidance control over his own actions insofar as they proceed from a 'weakly' reasons-responsive (deliberative) mechanism. This obtains just in case there is some *possible* scenario where the agent is presented with a sufficient reason to do otherwise and the mechanism that led to the actual choice is operative and it issues in a different choice, one appropriate to the imagined reason. In Fischer and Ravizza (1998), the account is elaborated and refined. They require, more strongly, that the mechanism be the person's own mechanism (ruling out external manipulation) and that it be 'moderately' responsive to reasons: one that is "regularly *receptive* to reasons, some of which are moral reasons, and at least weakly *reactive* to reason" (82, emphasis added). Receptivity is evinced through an understandable pattern of reasons recognition -- beliefs of the agent about what would constitute a sufficient reason for undertaking various actions. (See 69-73 for details.)

None of this, importantly, requires 'regulative' control: a control involving the ability of the agent to choose and act differently in the actual circumstances. Regulative control requires *alternative* possibilities open to the agent, whereas guidance control is determined by characteristics of the *actual* sequence issuing in one's choice. Fischer allows that there is a notion of freedom that requires regulative control but does not believe that this kind of freedom is required for moral responsibility. (In this, he is persuaded by a form of argument originated by Harry Frankfurt. See Frankfurt 1969 and Fischer 1994, Ch.7.)

3.2 Free Will as ultimate origination (ability to do otherwise)

Many do not follow Fischer here, however, and maintain the traditional view that the sort of freedom required for moral responsibility does indeed require that the agent could have acted differently. As Aristotle put it, "...when the origin of the actions is in him, it is also up to him to do them or not to do them" (1985, Book III).[3]

A flood of ink has been spilled, especially in the modern era, on how to understand the concept of being able to do otherwise. On one side are those who give it a deflationary reading, on which it is consistent with my being able to do otherwise that the past (including my character and present beliefs and desires) and the basic laws of nature logically entail that I do what I actually do. These are the 'compatibilists,' holding that freedom and causal determinism are compatible. (For discussion, see O'Connor, 2000, Ch.1; *compatibilism*; and *incompatibilism: arguments for*.) Conditional analyses of ability to do otherwise have been popular among compatibilists. The general idea here is that to say that I am able to do otherwise is to say that I *would* do otherwise if it were the case that ... , where the ellipsis is filled by some elaboration of "I had an appropriately strong desire to do so, or I had different beliefs about the best available means to satisfy my goal, or ... ." In short: something about my prevailing character or present psychological

states would have differed, and so would have brought about a different outcome in my deliberation.

Incompatibilists think that something stronger is required: for me to act with free will requires that there are a plurality of futures open to me consistent with the past (and laws of nature) *being just as they were*. I could have chosen differently even without some further, non-actual consideration's occurring to me and 'tipping the scales of the balance' in another direction. Indeed, from their point of view, the whole scale-of-weights analogy is wrongheaded: free agents are not mechanisms that respond invariably to specified 'motive forces.' They are capable of acting upon any of a plurality of motives making attractive more than one course of action. Ultimately, the agent must determine *himself* this way or that.

We may distinguish two broad families of 'incompatibilist' or 'indeterminist' self-determination accounts. The more radical group holds that the agent who determines his own will is not causally influenced by external causal factors, including his own character. Descartes, in the midst of exploring the scope and influence of 'the passions,' declares that "the will is by its nature so free that it can never be constrained" (1984, v.I, 343). And as we've seen, he believed that such freedom is present on every occasion when we make a conscious choice -- even, he writes, "when a very evident reason moves us in one direction...." (1984, v.III, 245). More recently, John Paul Sartre notoriously held that human beings have 'absolute freedom': "No limits to my freedom can be found except freedom itself, or, if you prefer, we are not free to cease being free." (567) His views on freedom flowed from his radical conception of human beings as lacking any kind of positive nature. Instead, we are 'non-beings' whose being, moment to moment, is simply to choose:

> For human reality, to be is to choose oneself; nothing comes to it either from the outside or from within which it can receive or accept....it is entirely abandoned to the intolerable necessity of making itself be, down to the slightest details. Thus freedom...is the being of man, i.e., his nothingness of being. (568-9)

Scotus and, more recently, C.A. Campbell, appear to agree with Descartes and Sartre on the lack of direct causal influence on the activity of free choice while allowing that the scope of possibilities for what I might thus will may be more or less constricted. So while Scotus holds that "nothing other than the will is the total cause" of its activity, he grants (with Aquinas and other medieval Aristotelians) that we are not capable of willing something in which we see no good, nor of positively repudiating something which appears to us as unqualifiedly good. Contrary to Sartre, we come with a 'nature' that circumscribes what we might conceivably choose, and our past choices and environmental influences also shape the possibilities for us at any particular time. But if we are presented with what we recognize as an unqualified good, we still can choose to *refrain from willing* it. And while Campbell holds that character cannot explain a free choice, he supposes that "[t]here is one experiential situation, and *one only*, ... in which there is any possibility of the act of will not being in accordance with character; viz. the situation in which the course which formed character prescribes is a course in conflict with the agent's moral ideal: in other words, the situation of moral temptation" (1967, 46). (Van Inwagen 1994 and 1995 is another proponent of the idea that free will is exercised in but a small subset of our choices, although his position is less extreme on this point than Campbell's. Fischer and Ravizza 1992 criticize van Inwagen's argument for this position, as does O'Connor 2000, Ch.5.)

A more moderate grouping within the self-determination approach to free will allows that beliefs, desires, and external factors all can causally influence the act of free choice itself. But theorists within this camp differ sharply on the metaphysical nature of those choices and of the causal role of reasons. We may distinguish three varieties. I will discuss them only briefly, as they are explored at length in *incompatibilist (nondeterministic) theories of free will*.

First is a noncausal (or ownership) account (Ginet 1990 and McCann 1998). According to this view, I control my choice simply in virtue of its being mine -- its occurring on[in] me. I do not exert any special kind of causality in bringing it about. While there may be causal influences upon my choice, there need not be, and any such causal influences wholly irrelevant to understanding why it occurs. Reasons provide an autonomous, non-causal form of explanation. Provided my choice is not wholly determined by prior factors, it is free and under my control simply in virtue of being mine.

Proponents of the event-causal account (e.g. Nozick 1995 and Ekstrom 2001) would say that uncaused events of any kind would be random and uncontrolled by anyone, and so could hardly count as choices that an agent *made*. They hold that reasons influence choices precisely by causing them. Choices are *free* insofar as they are not deterministically caused, and so might not have occurred in just the circumstances in which they did occur. A special case of the event-causal account of self-determination is Kane (1996). Kane believes that the free choices of greatest significance to an agent’s autonomy are ones that are preceded by efforts of will within the process of deliberation. These are cases where one’s will is conflicted, as when one’s duty or long-term self-interest compete with a strong desire for a short-term good. As one struggles to sort out and prioritize one’s own values, the possible outcomes are not merely undetermined, but also *indeterminate*: at each stage of the struggle, the possible outcomes have no specific objective probability of occurring. This indeterminacy, Kane believes, is essential to freedom of will.

Finally, there are those who believe freedom of will consists in a distinctively personal form of causality, commonly referred to as "agent causation." The agent himself causes his choice or action, and this is not to be reductively analyzed as an event within the agent causing the choice. (Compare our ready restatement of "the rock broke the window" into the more precise "the rock’s being in momentum M at the point of contact with the window caused the window’s subsequent shattering.") This view is given clear articulation by Thomas Reid:

> I grant, then, that an effect uncaused is a contradiction, and that an event uncaused is an absurdity. The question that remains is whether a volition, undetermined by motives, is an event uncaused. This I deny. The cause of the volition is the man that willed it. (Letter to James Gregory, in 1967, 88)

Roderick Chisholm advocated this view of free will in numerous writings (e.g., 1982 and 1976). And recently it has been developed in different forms by Randolph Clarke (1993, 1996) and O’Connor (2000). Nowadays, many philosophers view this account as of doubtful coherence (e.g., Dennett 1984).

For some, this very idea of causation by a substance just as such is perplexing (Ginet 1997). Others see it as difficult to reconcile with the causal role of reasons in explaining choices. (Clarke and O'Connor devote considerable effort to addressing this concern.) And yet others hold that, coherent or not, it is inconsistent with seeing human beings as part of the natural world of cause and effect (Pereboom 2001).

A recent trend is to suppose that agent causation accounts capture, as well as possible, our prereflective idea of responsible, free action. But the failure of philosophers to work the account out in a fully satisfactory and intelligible form reveals that the very idea of free will (and so of responsibility) is incoherent (Strawson 1986) or at least inconsistent with a world very much like our own (Pereboom 2001). Smilansky (2000) takes a more complicated position, on which there are two 'levels' on which we may assess freedom, 'compatibilist' and 'ultimate'. On the ultimate level of evaluation, free will is indeed incoherent.

4. Theological Wrinkles

A large portion of Western philosophical writing on free will was and is written within an overarching theological framework, according to which God is the ultimate source *and sustainer* of all else. Some of these thinkers draw the conclusion that God must be a sufficient, wholly determining cause for everything that happens; all suppose that every creaturely act necessarily depends on the explanatorily prior, cooperative activity of God. It is also presumed that human beings are free and responsible (on pain of attributing evil in the world to God alone, and so impugning His perfect goodness). Hence, those who believe that God is omni-determining typically are compatibilists with respect to freedom and (in this case) theological determinism. Edwards (1957) is a good example. But those who suppose that God's sustaining activity (and special activity of conferring grace) is only a necessary condition on the outcome of human free choices need to tell a more subtle story, on which omnipotent God's cooperative activity can be (explanatorily) prior to a human choice and yet the outcome of that choice be settled only by the choice itself. (For important medieval discussions -- the period of the apex of treatments of philosophical/theological matters -- see the relevant portions of Aquinas 1945 and Scotus 1994.)

Another issue concerns the impact on human freedom of knowledge of God, the ultimate Good. Many philosophers, especially the medieval Aristotelians, were drawn to the idea that human beings cannot but will that which they take to be an unqualified good. (Duns Scotus appears to be an important exception to this consensus.) Hence, in the afterlife, when humans 'see God face to face,' they will inevitably be drawn to Him. Murray (1993) is a contemporary development of the argument that a good God would choose to make His existence and character less than certain for human beings, for the sake of their freedom. (He will do so, the argument goes, at least for a period of time in which human beings participate in their own character formation.) If it is a good for human beings that they freely choose to respond in love to God and to act in obedience to His will, then God must maintain an 'epistemic distance' from them lest they be overwhelmed by His goodness and respond out of necessity, rather than freedom.

Finally, there is the question of the freedom of God himself. Perfect goodness is an essential, not

acquired, attribute of God. God cannot lie or be in any way immoral in His dealings with His creatures. Unless we take the minority position on which this is a trivial claim, since whatever God does *definitionally* counts as good, this appears to be a significant, inner constraint on God's freedom. Did we not contemplate immediately above that human freedom would be curtailed by our having an unmistakable awareness of what is in fact the Good? And yet is it not passing strange to suppose that God should be less than perfectly free?

One suggested solution to this puzzle begins by reconsidering the relationship of two strands in (much) thinking about freedom of will: being able to do otherwise and being the ultimate source of one's will. Contemporary discussions of free will often emphasize the importance of being able to do otherwise. Yet it's plausible (Kane 1996) that the core metaphysical feature of freedom is being the ultimate source, or originator, of one's choices, and that being able to do otherwise is closely connected to this feature. For human beings or any created persons who owe their existence to factors outside themselves, the only way their acts of will could find their ultimate origin in themselves is for such acts not to be determined by their character and circumstances. For if all my willings were wholly determined, then if we were to trace my causal history back far enough, we would ultimately arrive at external factors that gave rise to me, with my particular genetic dispositions. My motives at the time would not be the ultimate source of my willings, only the most proximate ones. Only by there being less than deterministic connections between external influences and choices, then, is it be possible for me to be an ultimate source of my activity, concerning which I may truly say, "the buck stops here."

As is generally the case, things are different on this point in the case of God. Even if God's character absolutely precludes His performing certain actions in certain contexts, this will not imply that some external factor is in any way a partial origin of His willings and refrainings from willing. Indeed, this would not be so even if he were determined by character to will everything which He wills. For God's nature owes its existence to nothing. So God would be the sole and ultimate source of His will even if He couldn't will otherwise.

Well, then, might God have willed otherwise in any respect? The majority view in the history of philosophical theology is that He indeed could have. He might have chosen not to create anything at all. And given that He did create, He might have created any number of alternatives to what we observe. But there have been noteworthy thinkers who argued the contrary position, along with others who clearly felt the pull of the contrary position even while resisting it. The most famous such thinker is Leibniz (1985), who argued that God, being both perfectly good and perfectly powerful, cannot fail to will the best possible world. Leibniz insisted that this is consistent with saying that God is able to will otherwise, although his defense of this last claim is notoriously difficult to make out satisfactorily. Many read Leibniz, *malgre lui*, as one whose basic commitments imply that God could not have willed other than He does in any respect.

On might challenge Leibniz's reasoning on this point by questioning the assumption that there is a uniquely best possible Creation (Adams 1987). One way this could be is if there is no well-ordering of worlds: some worlds are sufficiently different in kind that they are incommensurate with each other (neither is better than the other, nor are they equal). Another way this could be is if there is no upper limit

on goodness of worlds: for every possible world God might have created, there are others (infinitely many, in fact) which are better. If such is the case, one might argue, it is reasonable for God to arbitrarily choose which world to create from among those worlds exceeding some threshhold value of overall goodness.

However, William Rowe (1993) has countered that the thesis that there is no upper limit on goodness of worlds has a very different consequence: it shows that there could not be a morally perfect Creator! For suppose our world has an on-balance moral value of n and that God chose to create it despite being aware of possibilities having values higher than n that He was able to create. It seems we can now imagine a morally better Creator: one having the same options who chooses to create a better world. For a critical reply to Rowe, see the Howard-Snyders (1994) and Wainwright (1996).

Finally, Norman Kretzmann (1997, 220-25) has argued in the context of Aquinas's theological system that there is strong pressure to say that God must have created something or other, though it may well have been open to Him to create any of a number of contingent orders. The reason is that there is no plausible account of how an absolutely perfect God might have a *resistible* motivation -- one consideration among other, competing considerations -- for creating something rather than nothing. (It obviously cannot have to do with any sort of utility, for example.) The best general understanding of God's being motivated to create at all -- one which in places Aquinas himself comes very close to endorsing -- is to see it as reflecting the fact that God's very being, which is goodness, necessarily diffuses itself. Perfect goodness will naturally communicate itself outwardly; God who is perfect goodness will naturally create, generating a dependent reality that imperfectly reflects that goodness. (Wainwright (1996) is a careful discussion of a somewhat similar line of thought in Jonathan Edwards.)

Further Reading. Pereboom (1997) provides nice selections from a number of important historical writers on free will. Bourke (1964) and Dilman (1999) provide critical overviews of many such writers. For thematic treatments, see Kane (1996), esp. Ch.1-2; 5-6; Ekstrom (2001); and the lengthy survey articles in Kane (forthcoming).

Notes to Free Will

Notes

1. His view is discussed in several places. See, for example, *Summa Theologiae* I, q.82 (1945, vol.I) and *Questions on Evil*, q.6 (1993).

2. Plato's views on the soul and its powers are set in numerous places. See, e.g., *The Republic,* Book IV; *Phaedrus,* 237e-238e and 246-248; *Gorgias,* 466. All are found in (1997).

3. Note that Aristotle here sees origination in the agent and ability to do otherwise as closely related. Robert Kane (1996) suggests that while some form of ability to do otherwise is indeed necessary for moral responsibility, this condition is but an indicator of something deeper to free will: the willing's finding its *ultimate origin* in the agent.

Incompatibilist (Nondeterministic) Theories of Free Will

To act with free will is to exercise a certain type of control over one's behavior; what you do, when you act freely, is up to you. Incompatibilists hold that we exercise this control only if determinism is false. Many incompatibilists say little more about what, besides the falsehood of determinism, free will requires. And, indeed, the task of providing an incompatibilist account is not an easy one. For, if the truth of determinism would preclude free will, it is far from obvious how indeterminism would help.

Incompatibilist accounts that have been offered are of three main types, differing with respect to which form of indeterminism (uncaused events, nondeterministically caused events, agent- (or substance-) caused events) they require. Further variations among accounts concern where in the processes leading to actions they require indeterminism and what other conditions besides indeterminism they require. The first three sections below examine recent versions of each of the three main types of incompatibilist view. The fourth section considers the evidence regarding whether in fact there does exist what any of these accounts characterizes.

---

1. Noncausal Accounts

Some nondeterministic accounts require that a free decision or other free action have no cause at all; some require that it either have no cause or be only nondeterministically caused by prior events. Since both such views place no positive causal requirements on free action, we may call them "noncausal accounts."

Proponents of noncausal views generally hold that every action is or begins with a mental action. A decision or a choice is typically held to be an example of an action that is just such a mental action. An overt bodily action, such as raising one's arm, is held to be a complex action consisting of a mental action's bringing about a certain motion of one's body. The mental action here is often called a volition, which is said to be the agent's willing, trying, or endeavoring to move a certain part of her body in a certain way.

Ginet (1990) and McCann (1998) have set out the most fully developed recent noncausal views of free will. Other recent views of this type are advanced by Goetz (1988 and 1997) and McCall (1994: ch. 9).

Both Ginet and McCann hold that some event involving an agent is a basic action in virtue of its possessing some intrinsic feature. On Ginet's view, the feature in question is an "actish phenomenal quality," which he describes as its seeming to the agent as if she is directly producing the event that has this quality. McCann holds that the feature that characterizes these basic actions is intrinsic intentionality. For example, when one makes a decision, he holds, intrinsic to the decision is one's intending to make that very decision. (E.g., when one decides to A, one intends to decide to A.) One's so intending is not a matter of the content of the intention that is formed in deciding, nor is it a matter of one's having any further intention in addition to that formed in making the decision. Rather, McCann holds, it is a matter of a decision's being, by its very nature, an exercise of agency.

As is characteristic of proponents of noncausal accounts, neither Ginet nor McCann place any additional positive requirements on free action; the further requirements are instead that certain conditions be absent. Both require that the action not be causally determined. Ginet requires, further, that in performing the action, the agent not be subject to irresistible compulsion.

Two main problems arise for noncausal accounts of free will; both are problems, in the first instance, for noncausal accounts of action. The first concerns control. Performing an action, even acting unfreely, is exercising some variety of active control over one's behavior. Acting freely is exercising an especially valuable variety of active control. An account of free decision or other free action ought to say what this latter variety of control is or in what it consists. A common objection is that noncausal accounts fail to meet this requirement.

The second main problem concerns rationality. Acting freely is acting with a capacity for rational self-governance and determining, oneself, whether and how one exercises that capacity on a given occasion. Hence it must be possible for a free action to be an action performed for a certain reason, an action for which there is a rational explanation. Again, it is often objected that noncausal views cannot provide adequate accounts of these phenomena.

1.1 Control

An obvious candidate for an account of active control is that an agent's exercising such control consists

in her action's being caused, in an appropriate way, by her, or by certain events involving here, such as her having certain beliefs and desires and a certain intention. Noncausal views reject such an account; let us consider some alternatives.

On Ginet's view, the single positive characteristic present in all actions is the actish phenomenal quality, its seeming to the agent as if she is directly making happen the event that is her action. But it cannot be true, he holds, that we are agent-causes of our actions, nor need it be the case that any events involving us cause them. Ginet stresses that his description of this quality is metaphorical; the experience does not literally represent to the agent that she is bringing about the event in question.

Whatever the correct characterization of this phenomenal quality, it may be objected that the mere feel of a mental event, although it may be a (more or less reliable) sign of an individual's active control over that event, cannot itself *constitute* such control. The objection is reinforced by the fact that, on Ginet's view, an event with this quality could be brought about by external brain stimulation, in the absence of any relevant desire or intention in the "agent."

McCann holds that an agent's exercise of control has two aspects: it is a spontaneous, creative undertaking on the part of the agent, and it is intrinsically intentional. Causal theorists of action deny that the intentionality of, say, one's acquisition of an intention when one makes a decision can be intrinsic to that event. McCann observes that it is impossible for a decision to be unintentional, and he concludes from that observation that the intentionality must then be intrinsic to the decision. However, as Mele (1997) points out, an alternative explanation of this impossibility is available. For something to count as a decision, a causalist may hold, one's acquisition of an intention (to pursue some more or less specific course of action) must be caused, in an appropriate way, by one's having an intention to make up one's mind about what to do. Given the requirement of such a causal history, the causalist alternative continues, necessarily any event that is a decision is intentional. But this says nothing about the intrinsic features of decisions (any more than the fact that nothing counts as sunburn unless it is caused by the sun says anything about the intrinsic features of the burns that are so-caused).

The spontaneity of actions, McCann holds, "has a certain *sui generis* character that renders it incapable of being reduced to anything else" (p. 185). Such a claim suggests that no explication of active control is possible. This might be so if active control is a metaphysically simple phenomenon, a fundamental feature of the world. Causalists may object here that active control is comprehensible only as a causal phenomenon. Further, if active control is a simple phenomenon, then it would be emergent, a higher-level phenomenon appearing only in mentally sophisticated beings and yet not constituted by any lower-level phenomena. The question then arises whether there is evidence that there exist any such emergent, higher-level, metaphysically basic phenomena.

1.2 Rational Explanation

Turning now to acting for certain reasons and to rational explanation, again obvious candidates for accounts of the phenomena invoke causation: an agent acts for a certain reason only if the agent's having

that reason causes, in an appropriate way, the agent's behavior, and citing a reason contributes to a rational explanation of an action only if the agent's having that reason caused, in an appropriate way, the action. Let us consider alternatives offered by noncausalists.

Suppose that *S* wants her glasses, which she has left in her friend *R*'s room, where he is now sleeping. *S* also wants to wake *R*, because she desires his company, but she know that *R* needs some sleep, and hence she desires, too, not to wake him. *S* enters *R*'s room and retrieves her glasses, knowing as she does so that her action will satisfy her desire to wake *R*. What further facts about the situation could make it the case that *S* acts on her desire to get her glasses, and that citing that desire provides a true rational explanation of her action, while she does not act on her desire to wake *R*, and citing this latter desire does not give us a true rational explanation of what she did? Ginet maintains that the following conditions suffice for the truth of the explanation that cites *S*'s desire to get her glasses:

> (a) prior to entering the room, *S* had a desire to get her glasses, and
>
> (b) concurrently with her entering the room, *S* remembered that prior desire and intended of her entering the room that it satisfy (or contribute to satisfying) that desire.

Citing *S*'s desire to wake *R* will fail to give us a true rational explanation, Ginet holds, just in case *S* did not intend of her action that it satisfy (or contribute to satisfying) that desire.

Several objections may be raised against this account. Suppose that *S*'s desire to get her glasses played no role at all in bringing about her action, while her desire to wake *R*, of which she was fully aware when she acted, did play such a role. Causalists (see, e.g., Mele (1992: ch. 13)) will then deny that *S* really acted on her desire to get her glasses and that citing it truly explains her action. Moreover, Ginet's memory condition may not be necessary. If *S*'s desire to get her glasses is retained and remains fully conscious while she acts, there may be no need for her to remember it in order for her to be acting on it. Further problems attend the concurrent intention that is required. (McCann (1998: 162-63) raises some of these difficulties.) First, the required intention is a second-order attitude, an attitude about (among other things) another of the agent's own attitudes (a certain desire of hers). But it seems that *S* might act on her desire to get her glasses even if her only intention when she enters the room is to retrieve her glasses. Second, the concurrent intention to which Ginet appeals is said to make direct (or demonstrative) reference to the action, and Ginet holds that such direct reference requires that the intention be caused by the action (or at least by some initial segment of it). If that is so, then at least some part of the action has occurred before the concurrent intention is acquired. It does not then seem that the acquisition of that intention can figure in an account of what, if anything, rationally explains that part of the action. Finally, intention-acquisitions themselves can be explained by citing reasons. Since Ginet's account of the rational explanation of an action appeals to an intention, the question arises what can be said about the rational explanation of the acquisition of that intention. Repeating the same sort of account here would generate a regress, and Ginet offers no other sort.

On McCann's view, an agent decides for a certain reason, and citing that reason rationally explains the

decision, just in case, in cognizance of that reason, and in an intrinsically intentional act of intention formation, the agent forms an intention the content of which reflects the very goals presented in that reason. When *S* decides to enter *R*'s room, for example, she decides for the reason of getting her glasses only if the intention that she forms in making that decision is an intention to enter for the sake of getting her glasses. But such correspondence between the reasons for which one decides and the content of the decision may be too much to require. *S* may want her glasses so that she can finish reading a certain novel, which she may want to do so that she can contribute to the discussion in her book club tomorrow. Finishing the novel and getting ready for tomorrow's discussion may be among the reasons for which she decides to enter the room even if they are not included in the content of her decision. Finally, there will again be a clash of intuitions here between causalists and noncausalists, with the former maintaining that if *S*'s desire to get her glasses plays no role at all in bringing about her decision, then even if the content of her decision is to enter for the sake of getting her glasses, she does not really decide for that reason and citing it does not truly explain her decision. (One does not, the objection goes, make it so just by intending it to be so, no even by intrinsically intentionally intending it to be so.)

We have considered problems for noncausal accounts of *action*. However, since the noncausal views examined here place no positive requirements on *free action* beyond those that are placed on action, if they fail as adequate accounts of action, then *a fortiori* they fail as adequate accounts of free action.

2. Event-Causal Accounts

Compatibilist accounts of free action are typically event-causal accounts, invoking event-causal accounts of action. The simplest event-causal incompatibilist view takes the requirements of a good compatibilist account and adds that certain agent-involving events that cause the action must nondeterministically cause it. When these conditions are satisfied, it is held, the agent exercises in performing her action a certain variety of active control (which is said to consist in the action's being caused by those agent-involving events), the action is performed for reasons, and there was a chance of the agent's not performing that action. It is thus said to have been open to the agent to do otherwise, even given that (it is claimed) its being so open is incompatible with the truth of determinism.

One common objection against such a view is that the indeterminism that it requires is destructive, that it would diminish the control with which an agent acts. A second common objection is that the required indeterminism is gratuitous, that it adds nothing of value. We shall examine these objections below. First, let us consider a type of event-causal nondeterministic account that is advocated by writers who accept a qualified version of the first of these objections.

2.1 Deliberative Indeterminism

Some writers accept that indeterminism located in the immediate causation of a decision or other action would diminish control but hold that indeterminism confined to earlier stages in the processes leading to decision need not do so. Ekstrom (2000) and Mele (1995, 1996, and 1999b) have advanced the most fully

developed recent nondeterministic accounts of this sort. Such views have also been sketched by Dennett (1978) and Fischer (1995).

Overt action is sometimes preceded by a decision, and decision is sometimes preceded by a deliberative process in which the agent considers reasons for and against alternatives and makes an evaluative judgment concerning which alternative is best (or better or good enough). Focusing on decisions that follow such deliberation, Mele advances a view that allows (but does not require) the deterministic causation of the decision by the making of the judgment, and of the overt action by the decision. Indeterminism is required only at an earlier stage of the deliberative process. For example, the account is satisfied when it is undetermined which of a certain subset of the agent's nonoccurrent beliefs come to mind in the process of deliberation, where their coming to mind combines with other events to bring about the agent's evaluative judgment. (The subset in question consists of "beliefs whose coming or not coming to mind is not something that one would control even if determinism were true" (1995: 216).)

Mele argues that indeterminism of the sort required here does not diminish, at least not to any significant extent, "proximal control," a variety of control that is compatible with determinism. The required indeterminism nevertheless suffices, he holds, to provide the agent with "ultimate control" over her decision, which an agent has only if at no time prior to the decision is there any minimally causally sufficient condition for the agent's making that decision that includes no event or state internal to the agent.

In Ekstrom's account, the notion of preference, rather than that of an evaluative judgment, plays a prominent role. A preference, as she understands it, is a desire "formed by a process of critical evaluation with respect to one's conception of the good" (p. 106). The formation of a preference, she maintains, is an action. She requires indeterminism only in the production of these preferences. A decision or subsequent action is free, on her view, just in case it is brought about, in an appropriate way, by an active formation of a preference (favoring that decision or action), which preference-formation is in turn the result of an uncoerced exercise of the agent's evaluative faculty, the inputs to which (the considerations taken up in deliberation) nondeterministically cause the preference-formation.

Ekstrom holds that an agent *is* her preferences and acceptances (reflectively held beliefs), together with her faculty of forming these by reflective evaluation. When the formation of a preference is nondeterministically caused and it deterministically causes a decision and subsequent action, then, a preference that partly constitutes the agent, that is generated by an evaluative faculty that partly constitutes the agent, and that the agent could have prevented (by not forming that preference) causally determines the decision and subsequent action. What the agent does is then, Ekstrom holds, up to her.

Mele's and Ekstrom's views both allow that a free decision or other free action may be causally determined by events none of which are free actions. Indeed, on pain of regress, both must allow that a free decision or other free action may be causally determined by events none of which are free actions and to none of which has the agent contributed by her performance of any free action. (A familiar regress would be generated if, in order for a decision or other action to be free, it were required that it result from

the making of an evaluative judgment or the formation of a preference that was either itself a free action or to which the agent had contributed by her performance of some other free action.) Incompatibilists will typically not allow such a thing. Hence, an incompatibilist who finds either of these views acceptable will have something other than the typical incompatibilist's reasons for rejecting compatibilism.

2.2 Efforts of Will

Event-causal accounts of a more typical sort require that, for at least some free actions, there be nondeterministic causation of the free actions themselves. The most sophisticated recent account of this sort is that advanced by Kane (1996, 1999a, 1999b, and 2000). Other views of this type are sketched by Nozick (1981: 294-316), Sorabji (1980: ch. 2), van Inwagen (1983: 137-50), and Wiggins (1973).

A free decision or other free action, Kane holds, is one for which the agent is "ultimately responsible." Ultimate responsibility for an action requires either that the action not be causally determined or, if the action is causally determined, that some (nonredundant) part of any determining cause of it either be or result from some action by that agent that was not causally determined (and for which the agent was ultimately responsible). Thus, on Kane's view, an agent may be ultimately responsible for a decision that is causally determined by factors that include her having certain character traits. But somewhere among the events that contributed (however indirectly) to those traits, and thus to her decision, there must have been some actions by her that were not causally determined. Kane calls such "regress-stopping" actions "self-forming actions." All self-forming actions, he argues, are acts of will; they are mental actions. He thus calls them "self-forming willings," or SFWs. Kane identifies six different types of SFWs, giving the most detailed treatment to what he calls moral choices or decisions and prudential choices or decisions. We shall focus here on the former; the two are sufficiently similar that the points made here can be easily transferred to the latter.

In a case of moral choice, there is a motivational conflict within the agent. She believes that a certain type of thing morally ought to be done (and she is motivated to do that), but she also has a self-interested desire to perform an action of a type that is, in the circumstances, incompatible with her doing what she believes she ought to do. Given her commitment to her moral belief, she makes an effort of will to resist temptation, an effort "to get [her] ends or purposes sorted out" (1996: 126). If the choice is to be a SFW, then it is required that the strength of this effort be indeterminate; Kane likens its indeterminacy to that of the position or momentum of a microphysical particle. And the effort's indeterminacy is held to be the source of the required indeterminism in the causal production of the choice. Again an analogy is drawn with microphysics. Just as whether a particle will penetrate a barrier may be undetermined because the particle's position and momentum are not both determinate, so "[t]he choice one way or the other is *undetermined* because the process preceding and potentially terminating in it (i.e., the effort of will to overcome temptation) is *indeterminate*" (1996: 128).

Kane further requires that any choice that is a SFW satisfy three plurality conditions. These require that the choice be made for reasons (which Kane takes to consist partly in the choice's being caused by the

agent's having those reasons) and that it not be a result of coercion or compulsion. Each plurality condition also requires that, when the agent makes the choice, she wants more to act on the reasons for which she makes that choice than she wants to act on any competing reasons. An agent wants more to act on certain reasons, he holds, when her desire to act on those reasons has greater motivational strength than have any desires she has to act on competing reasons, and when it is settled in the agent's mind that those reasons, rather than her reasons for doing otherwise, are the ones that she will now and in the future act on. This wanting more to act on certain reasons is, on Kane's view, brought about by the choice in question. Finally, the plurality conditions require that, whichever choice is made, there have been at least one alternative choice that the agent was able to make such that, had she made it, it too would have satisfied the previously stated conditions.

In a situation of moral conflict, Kane maintains, the requirements for being a SFW may be satisfied by either choice that is made--the choice to do what one believes one ought to do or the choice to do what one is tempted to do. Where this is so, whichever choice the agent makes, she has chosen for the reasons that she wants more to act on, free from coercion and compulsion. If she has chosen to do what she believes she ought to do, then her choice is the result of her effort. If she has chosen to do what she was tempted to do, then she has not allowed her effort to succeed. Whichever choice she has made, she could have made the other. She is then ultimately responsible for the choice she has made.

Kane's requirement that the causation of a choice that is a SFW be nondeterministic has drawn the objection that indeterminism located here would diminish the agent's control over the making of the choice. The objection is often couched in terms of a problem of luck. (It is so developed by Haji (1999), Mele (1998, 1999a, and 1999b), and Strawson (1994).) If the agent's effort of will nondeterministically causes her choice, then, whichever choice the agent makes, there was, until the occurrence of that choice, a chance that it would not occur. If the agent's effort to chose in accord with her moral judgment happens to succeed, the objection goes, then her choice is at least partly due to good luck. In another possible world, with exactly the same laws of nature and exactly the same in its course of events up until the occurrence of the choice, the agent's (or her counterpart's) effort fails; there, but for good luck, goes she. And analogously, if, in the actual world, the agent's effort fails, then her choice is at least partly due to bad luck. Either way, the choice is to some degree due to luck. And to that degree, the objection concludes, the control that the agent exercises in making the choice is diminished.

Kane offers a complex reply to this objection. First, he counters that with indeterminate events, exact sameness is not defined. If an agent's effort of will was indeterminate, then it cannot be that she and her counterpart made exactly the same effort, and one got lucky while the other did not. An objection that assumes that such exact sameness is possible, he holds, does not apply to his view. Kane infers from this point that free will requires a form of indeterminism in which there is chance as well as indeterminacy, with the former stemming from the latter. (He calls worlds with such indeterminism "non-Epicurean.") The chance in an Epicurean world (an indeterministic world without indeterminacy), he implies, would constitute control-diminishing luck.

Kane's claim that indeterminacy precludes exact sameness has been contested (see Clarke (1999) and O'Connor (1996)). And Haji (1999) and Mele (1999a and 1999b) contend that the argument from luck is

just as effective if we consider an agent and her counterpart who is as similar as can be, given the indeterminacy of their efforts. Indeed, the argument might be advanced without any appeal to other worlds or counterparts: given that there is a chance that the effort will fail, the agent is lucky, it may be said, if it succeeds.

A further reply from Kane to the argument from luck appeals to the active nature of efforts of will. When an agent makes an effort to choose to do what she believes she ought to do, she actively tries to bring about a certain choice. When the agent makes that choice, she succeeds, despite the indeterminism, at doing what she was (actively) trying to do. And Kane points out that typically, when this is so, the indeterminism does not undermine responsibility (and hence it does not so diminish active control that there is not enough for responsibility). He describes a case (1999b: 227) in which a man hits a glass table top attempting to shatter it. Even if it is undetermined whether his effort will succeed, Kane notes, if the man does succeed, he may well be responsible for breaking the table top.

If left here, the reply would fail to address the problem of luck in a case where the agent chooses to do what she is tempted to do rather than what she believes she ought to do. In response to this shortcoming, Kane has recently proposed a "doubling" of effort in cases of moral conflict. In such a case, he now holds, the agent makes two, simultaneous efforts of will, both indeterminate in strength. The agent tries to make the moral choice, and at the same time she tries to make the self-interested choice. Whichever choice she makes, then, she succeeds, despite the indeterminism, at doing something that she was actively trying to do.

This doubling of efforts of will introduces a troubling incoherence into case of moral conflict. If an agent is actively trying, at one time, to do two obviously incompatible things, that fact raises a serious question about the agent's rationality.

A further question concerns the efficacy of the appeal to the active nature of these efforts. In the case of the man who breaks the table top, his breaking the table top is free (if it is) *not* just because it results from an active effort to break the table top, but because it results (we are to presume) from a *free* effort to break the table top. A successful effort to make a certain choice can contribute in an analogous way to the choice's being free, then, only if the effort itself is free. What is needed, then, is an account of the freedom-level active control with which the agent acts in making these efforts of will.

Kane maintains that, although the effort of will that precedes a choice that is a SFW must be an action for which the agent is ultimately responsible, the effort need not itself be a SFW; it is allowed that the effort be causally determined. However, if the agent is ultimately responsible for the effort and it is causally determined, then the agent must, on his view, have contributed (however indirectly), by her performance of at least one earlier SFW, to the effort in question. Since, on Kane's account, all SFWs either are efforts of one sort or another or must be preceded by efforts, the task of providing an account of the freedom of an effort cannot be avoided.

Kane faces the following dilemma in providing such an account. If the account of the freedom of an

effort of will requires that the effort itself result from a prior free effort, then a vicious regress looms. On the other hand, if the account of the freedom of an effort of will need not appeal to any prior free efforts of will, then it would seem that the account of a regress-stopping free choice could likewise dispense with such an appeal.

2.3 A Simpler View

Kane's appeal to indeterminate efforts of will, and the appeal thereby to non-Epicurean indeterminism, do not appear to help meet the objection that indeterminism located in the causation of decisions or other actions themselves diminishes control. (Neither does it appear that help comes from his requirement that, in making a choice that is a SFW, the agent come to want more to act on the reasons for which she makes that choice. For, on Kane's view, this wanting more is brought about by the choice. And, if an event-causal view is on the right track, the agent's control over the making of the choice is a matter of the production of the choice, not of what the choice produces.) A far simpler event-causal incompatibilist account, then, may fare as well against the problem of control. How badly would it fare?

Suppose that Elena is considering whether to *A* or to *B*. She recognizes what she regards as a fairly strong reason to *A*, and she recognizes what she regards as a somewhat weaker reason to *B*. At a certain time, *t*, she decides to *A*. Consider a view on which the prior deliberative events nondeterministically cause that decision. The view need not require, though it may allow, that there was a chance that at *t* Elena would decide to *B*. Incompatibilism requires here that something other than deciding at *t* to *A* have been causally open, and that requirement will be met if there was a chance that at *t* Elena would continue deliberating, seeking further reasons for or against the two alternatives she is considering.

It certainly is not clear that the chance required here constitutes control-diminishing luck. However, the open alternatives required may not be sufficiently robust to satisfy many incompatibilists, who may want to require that, at least sometimes, when an agent makes a decision, there was a chance that at that time she instead make an alternative decision, even if any such alternative would have been contrary to her assessment of the reasons that she had recognized. Suppose the view requires that, in Elena's case, there have been a chance that she would at *t* decide to *B*. Does this sort of chanciness constitute control-diminishing luck?

Note that Elena's case will still differ from the following sort. Suppose that Lucas throws a dart, attempting to hit a target, which he succeeds in doing. Due to certain properties of the dart and the air, the process leading from his releasing the dart and ending in the dart's hitting the target was nondeterministic, and there was a chance of the dart's missing the target. Lucas exercises (indirect) active control over the dart's hitting the target only by way of his prior action of throwing the dart. The indeterminism in this case (in comparison with a case in which his throwing the dart causally determines its hitting the target) diminishes the chance of his succeeding at bringing about a nonactive result that he is actively trying to bring about. It is for this reason that indeterminism here constitutes control-diminishing luck.

But the indeterminism in Elena's case is located differently; it is located in the causal connection between certain nonactive events--Elena's recognizing and assessing certain reasons--and her performance of a basic action--her making a decision. She exercises active control over the making of the decision not by performing any prior action, but by making the decision. If indeterminism, in the form of nondeterministic causation, located here diminishes control, the explanation of why it does so will have to be different from the explanation of why the indeterminism in Lucas' case diminishes control. It is not obvious what this alternative explanation would be.

Even if the indeterminism required by an event-causal incompatibilist account does not diminish control, it does not appear to increase it, and a second objection may be raised, charging that the requirement is then gratuitous. In order to assess this second objection, it may prove helpful to reflect on why free will is important to us.

We value a freedom in acting that grounds dignity and responsibility, in the exercise of which we make a difference to the way the world goes, and one that accords with the appearance of openness that we find in deliberating. We can distinguish two aspects of this freedom: a kind of leeway or openness of alternatives, and a type of control that is exercised in action. The freedom in which we are interested for some of the above things may involve one but not the other of these aspects. (For example, Frankfurt (1969) has argued that an agent may be responsible for what she has done even if she could not have done otherwise.) In a similar fashion, it may be that what is gained with the indeterminism required by an event-causal incompatibilist account has to do with one but not the other of these aspects.

An agent's exercise of control in acting is her exercise of a positive power to determine what she does. If event-causal views are correct, this is a matter of the action's being caused, in an appropriate way, by certain events involving the agent, such has her having certain reasons and a certain intention. An event-causal incompatibilist account adds no new causes to those that can be required by a compatibilist account, and hence the former appears to add nothing to the agent's positive power to determine what she does. As far as this aspect of freedom is concerned, the requirement of indeterminism may well be (at best) superfluous.

But not so when it comes to the other aspect, the openness of more than one course of action. If incompatibilists are correct, there is never any such openness if the world is deterministic. The indeterminism required by an event-causal incompatibilist account suffices to secure this leeway or openness, and this may be important to us for several reasons. Some individuals, at least, may find that when they deliberate, they cannot help but presume that more than one course of action is genuinely open to them. If the world is in fact deterministic (and if incompatibilism is true), these individuals are subject to an unavoidable illusion (since we cannot avoid deliberating). And they may reasonably judge that it would be, for this reason, better if things are as presented in an event-causal incompatibilist view. Similarly, some individuals may reasonably judge that if things are as presented in this view, that is better with regard to our decisions' and other actions' making a difference to how the world goes. Of course, even if the world is deterministic, there is a way in which our decisions and other actions generally make a difference: had we not made those decisions and performed those actions, things would have gone differently. If things are as presented in an event-causal incompatibilist account, our decisions

and other actions still generally make a difference in this way. But they may make a difference in a second way as well: they may be branch points in a probabilistic unfolding of history, branch points over which we exercise active control. There may have been a real chance of things' not going a certain way, and these decisions and other actions may be the events that set things going that way. One may reasonably judge that it is better to be making a difference in this second as well as in the first way with one's decisions and other actions. Since we cannot be making a difference in this second way if the world is deterministic, some individuals may have reason to find that the indeterminism required by an event-causal incompatibilist view is not superfluous but adds something of value.

It is less clear that anything is to be gained with respect to responsibility. As was suggested above, it does not appear that on an event-causal incompatibilist account, agents exercise any greater positive powers of control than they could in a deterministic world. If Frankfurt is right, and the openness provided by such an account is not required for responsibility, then whether the account secures responsibility would appear to depend just on what positive powers of control it offers. Hence, if responsibility is not compatible with the truth of determinism, it may not be compatible with the truth of an event-causal incompatibilist account, either.

3. Agent-Causal Accounts

If, on an event-causal incompatibilist view, agents do not exercise any greater positive powers of control than they can on a compatibilist account, what type of incompatibilist view would secure greater control? A number of incompatibilists have maintained that such a view must hold that a free decision or other free action (or some component of it), while not causally determined by events, is caused by the agent, and that causation by an agent does not consist in causation by events (such as the agent's having certain reasons). An agent, it is said, is a continuant or substance, and hence not the kind of thing that can itself be an effect (though various events in its life can be). On these agent-causal accounts, then, an agent is in a strict and literal sense an originator of her free actions, an uncaused cause of her behavior. This combination of indeterminism and origination is thought to capture best the kind of freedom we desire with respect to dignity, responsibility, difference-making, and the appearance of openness.

An early advocate of this type of view was Reid (1969 [1788]). In recent years, agent-causal accounts have been advanced by Chisholm (1966), (1971), (1976a), (1976b), and (1978), Clarke (1993) and (1996), Donagan (1987), O'Connor (1995), (1996), and (2000), Rowe (1991), Taylor (1966) and (1992), Thorp (1980), and Zimmerman (1984).

Two main problems confront defenders of agent-causal accounts, one concerning the notion of agent causation and the other concerning the rational explicability of free decisions or other actions on such views.

All theorists who accept a causal construal of agents' control over what they do--and this includes most compatibilists as well as many incompatibilists--hold that, in a sense, agents cause their free actions. However, most hold that causation by an agent is just causation by certain events involving the agent,

such as the agent's having certain reasons and a certain intention. But, as we have seen, the agent causation posited by agent-causal accounts is held not to be this at all. It is said by most agent-causal theorists to be fundamentally different from event causation. And this raises the question whether any intelligible account of it can be given. Even some proponents of agent-causal views (e.g., Taylor and Thorp) seem doubtful about this, declaring agent causation to be strange or even mysterious.

Moreover, even if the notion of agent causation can be made intelligible, the question remains whether the thing itself--causation by a substance or continuant--is possible. An argument deriving from Broad (1952: 215) suggests that it is not. Each event, including each action, it is said, occurs at a certain time. And if an action is caused, the argument continues, then some part of that action's total cause must be an event, something that itself occurs at a certain time. Otherwise there would be no way to account for the action's occurring when it did. Hence, if an agent causes an action, there must be something the agent does, or some change the agent undergoes, that causes that action. Since either something the agent does or some change the agent undergoes would be an event, it is concluded, it cannot be the case, as most agent-causal accounts maintain, that free actions are caused by agents and not by any events.

The second main problem for agent-causal views stems from the fact that free actions can be performed for reasons and can be rationally explicable. We saw earlier that serious difficulties confront noncausal accounts of acting for certain reasons and of rational explanation. In denying, then, as most agent-causalists do, that free actions have any event causes, these theorists may rule out rational free action.

In response to this second problem, Clarke (1993 and 1996) proposes an agent-causal account on which a free action is caused by the agent *and* nondeterministically caused by certain agent-involving events, such as the agent's having certain reasons and a certain intention. Given this appeal to reasons-causation, the view can provide the same accounts of acting for reasons and of rational explanation as can event-causal views. And since the event causation that is posited is required to be nondeterministic, the view secures the openness of alternatives, even on the assumption that this openness is incompatible with determinism. Finally, the agent causation itself is still held to be distinct from causation by any events, and so this view secures the origination of free actions that seemed an appealing feature of more traditional agent-causal accounts.

Even though, on this type of agent-causal view, a free action is nondeterministically caused by events involving the agent, since the agent makes a further causal contribution to what she does in addition to the contribution made by those events, it would seem that she exercises greater positive powers of control than what could be exercised if all causes were events. Hence this type of account may have a stronger defense against the problem of control than have event-causal incompatibilist accounts.

This modification of traditional agent-causal views also addresses Broad's objection concerning the possibility of agent causation. That objection concludes that it cannot be the case that free actions are caused by agents and not by any events; if an agent causes an action, it is said, then some event involving that agent must cause the action and account for the action's occurring when it does. On the proposed view, some events involving the agent do cause each free action and account for the action's occurring

when it does.

O'Connor rejects this combination of agent and event causation. A free action, on his view, consists in an agent's causing a certain event, and he maintains that an agent's causing an event cannot be caused. O'Connor defends an account of rational explanation similar to that of Ginet, with an added requirement (for explanation that cites a certain desire) that the action begin with the agent's causing her acquisition of an intention to act so as to satisfy that desire.

Turning to the intelligibility of agent causation, O'Connor (1995, 1996, and 2000) and Clarke (1993 and 1996), though differing on details, have both suggested that agent causation might be characterized along the same lines as event causation, if the latter is given a nonreductive account. Familiar reductive accounts characterize event causation in terms of constant conjunction or counterfactual dependence or probability increase, and if event causation is so characterizable, then certainly agent causation would have to be fundamentally different. But if causation is a basic, irreducible feature of the world, then we might with equal intelligibility be able to think of substances as well as events as causes.

Even if we can understand the idea of agent causation, and even if the argument for its impossibility considered earlier is not effective, there remain reasons to doubt that it is possible for a substance to cause something. To give just one example, even if causation cannot be reduced to probability increase, it seems plausible that any cause must be the kind of thing that can affect the probability of its effect prior to the occurrence of that effect, even when the cause directly brings about that effect. Events are the sort of thing that can so affect probabilities, and this is due, it seems, to the fact that they occur at times. Substances do not occur (events involving them do), and they do not appear to be the sort of thing that can affect probabilities in the indicated way. This consideration, although not decisive, seems to count against the possibility of causation by a substance.

4. The Evidence

Our assessment of incompatibilist accounts so far has primarily focused on whether they satisfactorily characterize what free will would be, if there is such a thing. However, even if one or another of these views characterizes well the freedom that we value, and even if what that account characterizes is something that is possible, the question remains whether there is good evidence that what is posited by that account actually exists.

Incompatibilist accounts require, first, that determinism be false. But more than this, they require that there be indeterminism of a certain sort (e.g., with some events entirely uncaused, or nondeterministically caused, or caused by agents and not deterministically caused by events) and that this indeterminism be located in specific places (generally, in the occurrence of decisions and other actions). What is our evidence with regard to these requirements' being satisfied?

It is sometimes claimed (e.g., by Campbell (1957: 168-70) and O'Connor (1995: 196-97)) that our

experience when we make decisions and act constitutes evidence that there is indeterminism of the required sort in the required place. We can distinguish two parts of this claim: one, that in deciding and acting, things appear to us to be the way that one or another incompatibilist account says they are, and two, that this appearance is evidence that things are in fact that way. Some compatibilists (e.g., Mele (1995: 135-37)) deny the first part. But even if this first part is correct, the second part seems dubious. If things are to be the way they are said to be by some incompatibilist account, then the laws of nature--laws of physics, chemistry, and biology--must be a certain way. (This is so for overt, bodily actions regardless of the relation between mind and body, and it is so for decisions and other mental actions barring a complete independence of mental events from physical, chemical, and biological events.) And it is incredible that how things seem to us in making decisions and acting gives us insight into the laws of nature. Our evidence for the required indeterminism, then, will have to come from the study of nature, from natural science.

The scientific evidence for quantum mechanics is sometimes said to show that determinism is false. Quantum theory is indeed very well confirmed. However, there is nothing approaching a consensus on how to interpret it, on what it shows us with respect to how things are in the world. Indeterministic as well as deterministic interpretations have been developed, but it is far from clear whether any of the existing interpretations is correct. Perhaps the best that can be said here is that, given the demise of classical mechanics and electromagnetic theory, there is no good evidence that determinism is true.

The evidence is even less decisive with respect to whether there is the kind of indeterminism located in exactly the places required by one or another incompatibilist account. Unless there is a complete independence of mental events from physical events, then even for free decisions there has to be indeterminism of a specific sort at specific junctures in certain brain processes. There are some interesting speculations in the works of some incompatibilists about how this might be so (see, e.g., Kane (1996: 128-30 and 137-42) and the sources cited there); but our current understanding of the brain gives us no evidence one way or the other about whether it is in fact so. At best, it seems we must remain, for the time being, agnostic about this matter.

If incompatibilist free will requires agent causation, and if such a thing is possible, that is another requirement about which we lack evidence. Indeed, it is not clear that there could be any empirical evidence for or against this aspect of agent-causal views.

In sum, we do not have good evidence that any incompatibilist account is true. Some incompatibilists (e.g., van Inwagen (1983: 204-13)) hold that we nevertheless have good reason to believe that some such view is correct, since we have good reason to believe that we are morally responsible, that moral responsibility requires free will, and that free will requires indeterminism. However, lacking empirical evidence for the required indeterminism, if we justifiably believe the last two of the just mentioned propositions, then we have a strong moral reason not to treat each other as morally responsible. For if we are not responsible, then whenever we treat someone as responsible, we do that individual an injustice. And if indeterminism of a certain sort and in a certain location is required for responsibility and we lack evidence for the required indeterminism, then we risk this injustice whenever we treat someone as responsible. That is a strong moral reason (for incompatibilists) not to do so.

Moral Responsibility

When a person performs or fails to perform a morally significant action, we sometimes think that he or she is deserving of a particular kind of response. Praise and blame are perhaps the most common forms this reaction takes. For example, one who encounters a car accident may be worthy of praise for having saved a child from inside the burning car, or alternatively, one may be worthy of blame for not having at least used one's cell phone to call for help. To regard such agents as worthy of one of these reactions is to ascribe moral responsibility to them on the basis of what they have done or left undone. (These are examples of other-directed ascriptions of responsibility. The reaction might also be self-directed, e.g., one can recognize oneself to be blameworthy). Thus, to be morally responsible for something, say an action, is to be worthy of a particular kind of reaction -- praise, blame, or something akin to these -- for having performed it.[1]

Though further elaboration and qualification of the above characterization of moral responsibility is called for and will be provided below, this is enough to distinguish concern about this form of responsibility from some others commonly referred to through use of the terms ‘responsibility’ or ‘responsible.’ To illustrate, we might say that higher than normal rainfall in the spring is responsible for an increase in the amount of vegetation or that it is the judge's responsibility to give instructions to the jury before they begin deliberating. In the first case, we mean to identify a causal connection between the earlier amount of rain and the later increased vegetation. In the second, we mean to say that when one assumes the role of judge, certain duties, or obligations, follow. Although these concepts are connected with the concept of moral responsibility, they are not the same, for in neither case are we directly concerned about whether it would be appropriate to react to some candidate (here, the rainfall or a particular judge) with something like praise or blame.[2]

Philosophical reflection on moral responsibility has a long history. One reason for this persistent interest is the way the topic seems connected with a widely shared conception of ourselves as members of an importantly distinct class of individuals -- call them ‘persons.’[3] Persons are thought to be qualitatively different from those of other known living species, despite their numerous similarities. Many have held that one distinct feature of persons is their status as morally responsible agents, a status resting, perhaps, on a special kind of control only they can exercise. Many who view persons in this way have wondered whether their special status is threatened if certain other claims about our universe are true. For example, can a person be morally responsible for her behavior if that behavior can be explained solely by reference to physical states of the universe and the laws governing changes in those physical states, or solely by reference to the existence of a sovereign God who guides the world along a divinely ordained path? Concerns like these have often motivated individuals to theorize about moral responsibility.

A comprehensive theory of moral responsibility would elucidate the following: (1) the concept, or idea, of moral responsibility itself; (2) the criteria for being a moral agent, i.e., one who qualifies generally as an agent open to responsibility ascriptions (e.g., only beings possessing the general capacity to evaluate reasons for acting can be moral agents); (3) the conditions under which the concept of moral responsibility is properly applied, i.e., those conditions under which a moral agent is responsible for a particular something (e.g., a moral agent can be responsible for an action she has performed only if she performed it freely, where acting freely entails the ability to have done otherwise at the time of action); and finally 4) possible objects of responsibility ascriptions (e.g., actions, omissions, consequences, character traits, etc.). Although each of these will be touched upon in the discussion below (see, e.g., the brief sketch of Aristotle's account in the next section), the primary focus of this entry is on the first component --i.e., the concept of moral responsibility. The first section below is a discussion of the origin and history of Western reflection on moral responsibility. This is followed by a sketch of recent work on the concept of moral responsibility. For further discussion of issues associated with moral responsibility, see the related entries below.

Some Historical Background

What follows in this section is a brief outline of the origins and trajectory of reflection on moral responsibility in the Western philosophical tradition. Against this background, a distinction will be drawn between two conceptions of moral responsibility that have exerted considerable influence on subsequent thinkers.

An understanding of the concept of moral responsibility and its application is present implicitly in some of the earliest surviving Greek texts, i.e., the Homeric epics (circa 8th century BCE but no doubt informed by a much earlier oral tradition).[4] In these texts, both human and superhuman agents are often regarded as fair targets of praise and blame on the basis of how they have behaved, and at other times, an agent's behavior is excused because of the presence of some factor that has undermined his/her control (Irwin, 1999, p. 225). Reflection on these factors gave rise to *fatalism* -- the view that one's future or some aspect of it is predetermined, e.g., by the gods, or the stars, or simply some facts about truth and time -- in such a way as to make one's particular deliberations, choices and actions irrelevant to whether that particular future is realized (recall, e.g., the plight of Oedipus). If some particular outcome is fated, then it seems that the agent concerned could not be morally responsible for that outcome. Likewise, if fatalism were true with respect to all human futures, then it would seem that no human agent could be morally

responsible for anything. Though fatalism has sometimes exerted significant historical influence, most philosophers have rejected it on the grounds that there is no good reason to think that our futures are fated in the sense that they will unfold no matter what particular deliberations we engage in, choices we make, or actions we perform.

Aristotle (384-323 BCE) seems to have been the first to construct explicitly a theory of moral responsibility.[5] In the course of discussing human virtues and their corresponding vices, Aristotle pauses in *Nicomachean Ethics* III.1-5 to explore their underpinnings. He begins with a brief statement of the concept of moral responsibility -- that it is sometimes appropriate to respond to an agent with praise or blame on the basis of her actions and/or dispositional traits of character (1109b30-35). A bit later, he clarifies that only a certain kind of agent qualifies as a moral agent and is thus properly subject to ascriptions of responsibility, namely, one who possess a capacity for decision. For Aristotle, a decision is a particular kind of desire resulting from deliberation, one that expresses the agent's conception of what is good (1111b5-1113b3). The remainder of Aristotle's discussion is devoted to spelling out the conditions under which it is appropriate to hold a moral agent blameworthy or praiseworthy for some particular action or trait. His general proposal is that one is an apt candidate for praise or blame if and only if the action and/or disposition is voluntary. According to Aristotle, a voluntary action or trait has two distinctive features. First, there is a control condition: the action or trait must have its origin in the agent. That is, it must be up to the agent whether to perform that action or possess the trait -- it cannot be compelled externally. Second, Aristotle proposes an epistemic condition: the agent must be aware of what it is she is doing or bringing about (1110a-1111b4).[6]

There is an instructive ambiguity in Aristotle's account of responsibility, an ambiguity that has led to competing interpretations of his view. Aristotle aims to identify the conditions under which it is appropriate to praise or blame an agent, but it is not entirely clear how to understand the pivotal notion of appropriateness in his conception of responsibility. There are at least two possibilities: a) praise or blame is appropriate in the sense that the agent *deserves* such a response, given his behavior and/or traits of character; or b) praise or blame is appropriate in the sense that such a reaction is likely to bring about a desired consequence, namely an improvement in the agent's behavior and/or character. These two possibilities may be characterized in terms of two competing interpretations of the concept of moral responsibility: 1) the *merit-based view*, according to which praise or blame would be an appropriate reaction toward the candidate if and only if she merits -- in the sense of ‘deserves’ -- such a reaction; vs. 2) the *consequentialist view*, according to which praise or blame would be appropriate if and only if a reaction of this sort would likely lead to a desired change in the agent and/or her behavior.[7]

Scholars disagree about which of the above views Aristotle endorsed, but the importance of distinguishing between them grew as philosophers began to focus on a newly conceived threat to moral responsibility. While Aristotle argued against a version of fatalism (*On Interpretation*, ch. 9), he may not have recognized the difference between it and the related possible threat of *causal determinism* (contra Sorabji). Causal determinism is the view that everything that happens or exists is caused by sufficient antecedent conditions, making it impossible for anything to happen or be other than it does or is. One variety of causal determinism, *scientific determinism*, identifies the relevant antecedent conditions as a combination of prior states of the universe and the laws of nature. Another, *theological determinism*,

identifies those conditions as being the nature and will of God. It seems likely that theological determinism evolved out of the shift, both in Greek religion and in Ancient Mesopotamian religions, from polytheism to belief in one sovereign God, or at least one god who reigned over all others. The doctrine of scientific determinism can be traced back as far as the Presocratic Atomists (5th cent. BCE), but the difference between it and the earlier fatalistic view seems not to be clearly recognized until the development of Stoic philosophy (3rd. cent. BCE). Though fatalism, like causal determinism, might seem to threaten moral responsibility by threatening an agent's control, the two differ on the significance of human deliberation, choice, and action. If fatalism is true, then human deliberation, choice, and action are completely otiose, for what is fated will transpire no matter what one chooses to do. According to causal determinism, however, one's deliberations, choices, and actions will often be necessary links in the causal chain that brings something about. In other words, even though our deliberations, choices, and actions are themselves determined like everything else, it is still the case, according to causal determinism, that the occurrence or existence of yet other things depends upon our deliberating, choosing and acting in a certain way (Irwin,1999, pp. 243-249; Meyer, 1998, pp. 225-227, and Pereboom).

Since the Stoics, the thesis of causal determinism and its ramifications, if true, have taken center stage in theorizing about moral responsibility. During the Medieval period, especially in the work of Augustine (354-430) and Aquinas (1225-1274), reflection on freedom and responsibility was often generated by questions concerning versions of theological determinism, including most prominently: a) Does God's sovereignty entail that God is responsible for evil?; and b) Does God's foreknowledge entail that we are not free and morally responsible since it would seem that we cannot do anything other than what God foreknows we will do? During the Modern period, there was renewed interest in scientific determinism -- a change attributable to the development of increasingly sophisticated mechanistic models of the universe culminating in the success of Newtonian physics. The possibility of giving a comprehensive explanation of every aspect of the universe -- including human action -- in terms of physical causes now seemed much more plausible. Many thought that persons could not be free and morally responsible if such an explanation of human action were possible. Others argued that freedom and responsibility would not be threatened should scientific determinism be true. In keeping with this focus on the ramifications of causal determinism for moral responsibility, thinkers may be classified as being one of two types: 1) an *incompatibilist* about causal determinism and moral responsibility -- one who maintains that if causal determinism is true, then there is nothing for which one can be morally responsible; or 2) a *compatibilist* -- one who holds that a person can be morally responsible for some things, even if both who she is and what she does is causally determined.[8] In Ancient Greece, these positions were exemplified in the thought of Epicurus (341-270 BCE) and the Stoics, respectively.

Above, an ambiguity in Aristotle's conception of moral responsibility was highlighted -- that it was not clear whether he endorsed a merit-based vs. a consequentialist conception of moral responsibility. The history of reflection on moral responsibility demonstrates that how one interprets the concept of moral responsibility strongly influences one's overall account of moral responsibility. For example, those who accept the merit-based conception of moral responsibility have tended to be incompatibilists. That is, most have thought that if an agent were to genuinely merit praise or blame for something, then he would need to exercise a special form of control over that thing (e.g., the ability at the time of action to both perform or not perform the action) that is incompatible with one's being causally determined. In addition

to Epicurus, we can cite early Augustine, Thomas Reid (1710-1796), and Immanuel Kant (1724-1804) as historical examples here. Those accepting the consequentialist conception of moral responsibility, on the other hand, have traditionally contended that determinism poses no threat to moral responsibility since praising and blaming could still be an effective means of influencing another's behavior, even in a deterministic world. Thomas Hobbes (1588-1679), David Hume (1711-1776), and John Stuart Mill (1806-1873) are, along with the Stoics, representatives of this view. This general trend of linking the consequentialist conception of moral responsibility with compatibilism about causal determinism and moral responsibility and the merit-based conception with incompatibilism continued to persist through the first half of the twentieth century.

Recent Work on the Concept of Responsibility

The issue of how best to understand the concept of moral responsibility is important, for it can strongly influence one's view of what, if any, philosophical problems might be associated with the notion, and further, if there are problems, what might count as a solution. As discussed above, philosophical reflection on moral responsibility has historically relied upon one of two broad interpretations of the concept: 1) the *merit-based view*, according to which praise or blame would be an appropriate reaction toward the candidate if and only if she merits -- in the sense of 'deserves' -- such a reaction; or 2) the *consequentialist view*, according to which praise or blame would be appropriate if and only if a reaction of this sort would likely lead to a desired change in the agent and/or her behavior. Though the consequentialist view has continued to garner support (see e.g., Schlick, 1966, Brandt 1992, Frankena 1963, ch. 4, Dennett 1984, ch. 7, and Kupperman 1991, ch. 3), work in the last 50 years on the concept of moral responsibility has increasingly focused on: a) offering alternatives to the two traditional interpretations of moral responsibility; and b) alternative versions of the merit-based view.

Increased attention to the practice of *holding* persons morally responsible has generated much of the recent work on the concept of moral responsibility. All theorists have recognized features of this practice -- inner attitudes and emotions, their outward expression in censure or praise, and the imposition of corresponding sanctions or rewards. However, most understood the inner attitudes and emotions involved to rest on a more fundamental theoretical judgment about the agent's *being* responsible. In other words, it was typically assumed that blame and praise depended upon a judgment, or belief (pre-reflective in most cases), that the agent in question had satisfied the objective conditions on being responsible. These judgments were presumed to be independent of the inner attitudinal/emotive states involved in holding responsible in the sense that reaching such judgments and evaluating them required no essential reference to the attitudes and emotions of the one making the judgment. For the holder of the consequentialist view, this is a judgment that the agent exercised a form of control that could be influenced through outward expressions of praise and blame in order to curb or promote certain behaviors. For those holding the merit view, it is a judgment that the agent has exercised the requisite form of metaphysical control, e.g., that she could have done otherwise at the time of action (Watson 1987, p. 258).

If holding responsible is best understood as resting on an independent judgment about being responsible, then it is legitimate to inquire whether such underlying judgments and their associated outward

expressions can be justified, as a whole, in the face of our understanding of the world, e.g., in the face of evidence that our world is possibly deterministic.[9] According to incompatibilists, a judgment that someone is morally responsible could never be true if the world were deterministic; thus praising and blaming in the merit-based sense would be beside the point. Compatibilists, on the other hand, contend that the truth of determinism would not undermine the relevant underlying judgments concerning the efficacy of praising and blaming practices, thereby leaving the rationale of such practices intact.

In his landmark essay, ‘Freedom and Resentment,’ P. F. Strawson (1962) sets out to adjudicate the dispute between those compatibilists who hold a consequentialist view of responsibility and those incompatibilists who hold the merit-based view.[10] Both are wrong, Strawson believes, because they distort the concept of moral responsibility by sharing the prevailing view sketched above -- the view of those who understand the practice of holding persons responsible to rest upon a theoretical judgment of their being responsible. According to Strawson, the attitudes expressed in holding persons morally responsible are varieties of a wide range of attitudes deriving from our participation in personal relationships, e.g., resentment, indignation, hurt feelings, anger, gratitude, reciprocal love, and forgiveness. The function of these attitudes is to express ". . . how much we actually mind, how much it matters to us, whether the actions of other people -- and particularly *some* other people -- reflect attitudes towards us of good will, affection, or esteem on the one hand or contempt, indifference, or malevolence on the other." (p. 5, author's emphasis) These attitudes are thus *participant reactive attitudes*, because they are: a) natural attitudinal reactions to the perception of another's good will, ill will, or indifference (pp. 4-6), and b) expressed from the stance of one who is immersed in interpersonal relationships and who regards the candidate held responsible as a participant in such relationships as well (p. 10).[11]

The reactive attitudes can be suspended or modified in at least two kinds of circumstances, corresponding to the two features just mentioned. In the first, one might conclude that, contrary to first appearances, the candidate did not violate the demand for a reasonable degree of good will. For example, a person's behavior may be *excused* when one determines that it was an accident, or one may determine that the behavior was *justified*, say, in the case of an emergency when some greater good is being pursued. In the second kind of circumstance, one may abandon the participant perspective in relation to the candidate. In these cases, one adopts the *objective standpoint*, one from which one ceases to regard the individual as capable of participating in genuine personal relations (either for some limited time or permanently). Instead, one regards the individual as psychologically/morally abnormal or undeveloped and thereby a candidate, not for the full range of reactive attitudes, but primarily for those objective attitudes associated with treatment or simply instrumental control. Such individuals lie, in some sense or to some varying extent, outside the boundaries of the moral community. For example, we may regard a very young child as initially exempt from the reactive attitudes (but increasingly less so in cases of normal development) or adopt the objective standpoint in relation to an individual we determine to be suffering from severe mental illness (P. F. Strawson, pp. 6-10, Bennett, p. 40, Watson 1987, p. 259-260, R. Jay Wallace, chs. 5-6).

The central criticism Strawson directs at both consequentialist and traditional merit views is that both have over-intellectualized the issue of moral responsibility, and it is this criticism that has rendered his view so influential in subsequent work.[12] The charge of over intellectualization stems from the

traditional tendency to presume that the rationality of holding a person responsible depends upon a judgment that the person in question has satisfied some set of objective requirements on being responsible (conditions on efficacy or metaphysical freedom) and that these requirements themselves are justifiable. Strawson, by contrast, maintains that the reactive attitudes are a natural expression of an essential feature of our form of life, in particular, the interpersonal nature of our way of life. The practice, then, of holding responsible -- embedded as it is in our way of life -- "neither calls for nor permits, an external 'rational' justification (p. 23)." Though judgments about the appropriateness of particular responses may arise (i.e., answers to questions like: Was the candidate's behavior really an expression of ill will?; or Is the candidate involved a genuine participant in the moral sphere of human relations?), these judgments are based on principles internal to the practice. That is, their justification refers back to an account of the reactive attitudes and their role in personal relationships, *not to some independent theoretical account of the conditions on being responsible*.

Given the above, Strawson contends that it is pointless to ask whether the practice of holding responsible can be rationally justified if determinism is true. This is either because it is not psychologically possible to divest ourselves of these reactions and so continually inhabit the objective standpoint, or even if that were possible, because it is not clear that rationality could ever demand that we give up the reactive attitudes, given the loss in quality of life should we do so. In sum, Strawson attempts to turn the traditional debate on its head, for now *judgments about being responsible* are understood in relation to the role reactive attitudes play in the *practice of holding responsible*, rather than the other way around. Whereas judgments are true or false and thereby can generate the need for justification, the desire for good will and those attitudes generated by it possess no truth value themselves, thereby eliminating any need for an external justification (Magill, p. 21, Double, 1996b, p. 848).

Strawson's concept of moral responsibility yields a compatibilist account of being responsible but one that departs significantly from earlier such accounts in two respects. First, Strawson's is a compatibilist view by default only. That is, on Strawson's view, the problem of determinism and freedom/responsibility is not so much *resolved* by showing that the objective conditions on being responsible are consistent with one's being determined but rather *dissolved* by showing that the practice of holding people responsible relies on no such conditions and therefore needs no external justification in the face of determinism. Second, Strawson's is a merit-based form of compatibilism. That is, unlike most former consequentialist forms of compatibilism, it helps to explain why we feel that some agents deserve our censure or merit our praise. They do so because they have violated, met, or exceeded our demand for a reasonable degree of good will. A number of compatibilists have followed Strawson in this regard, incorporating the reactive attitudes into their theories of moral responsibility in order to provide an account that reflects a merit-based conception of moral responsibility.

Most agree that Strawson's discussion of the reactive attitudes is a valuable contribution to our understanding of the practice of holding responsible, but many have taken issue with Strawson's contentions about the insular nature of that practice, namely a) that since propriety judgments about the reactive attitudes are strictly internal to the practice (i.e., being responsible is defined in relation to the practice of holding responsible), their justification cannot be considered from a standpoint outside that practice; and b) that since the reactive attitudes are natural responses deriving from our psychological

constitution, they cannot be dislodged by theoretical considerations. Responding to the first of these, some have argued that it does seem possible to critique existing practices of holding responsible from standpoints outside them. For example, one might judge that either one's own existing community practice or some other community's practice of holding responsible ought to be modified (Fischer and Ravizza, 1993, p. 18). If such evaluations are legitimate, then, contrary to what Strawson suggests, the justification of an existing practice can be questioned from a standpoint external to it. In other words, being responsible cannot be explicated strictly in terms of an existing practice of holding responsible. This, then, would suggest a possible role to be played by theoretical conditions on being responsible, whether they are compatibilist or incompatibilist in nature.

Replying to the second of the above contentions, some have argued that incompatibilist intuitions are embedded in the reactive attitudes themselves so that these attitudes cannot persist unless some justification can be given of them, or more weakly, that they cannot but be disturbed if something like determinism is true. Here, cases are often cited where negative reactive attitudes seem to be dispelled or mitigated upon learning that an agent's past includes severe deprivation and/or abuse. There is a strong pull to think that our reactive attitudes are altered in such cases because we perceive such a background to be deterministic. If this is the proper interpretation of the phenomenon, then it is evidence that theoretical considerations, like the truth of determinism, could in fact dislodge the reactive attitudes (Nagel, p. 125; Kane, 84-89; Galen Strawson, 1986, p. 88, Honderich, 1988, vol. 2: ch. 1; and replies by Watson, 1987, 1996, p. 240; and McKenna, 1998).

Finally, some have taken this last point -- that incompatibilist intuitions may be embedded in or necessarily linked to the reactive attitudes -- further, challenging Strawson's and others' assumption that the reactive attitudes form a unitary class with respect to issues of freedom and responsibility. Instead, this group argues that the reactive attitudes are linked to bifurcated and contradictory ideas about freedom and moral responsibility, suggesting some level of incoherence in the concepts themselves (Nagel, G. Strawson, 1986,105-117, 307-317; Honderich, 1988, vol. 2: ch. 1; Double, 1991; Double 1996a, chs. 6-7). Some, for example Ted Honderich, have argued that our idea of a free and responsible agent as *an originator* of action is incompatibilistic, while our idea of free and responsible action as *voluntary* is compatibilistic.[13] Reflection on causal determinism thus generates conflicting attitudes. Honderich believes that a compromise, of sorts, can be reached between these opposing ideas and associated attitudes given the truth of determinism -- that in spite of this one can train oneself to adopt a coherent and meaningful conception of both freedom and responsibility (Honderich, 1988, vol. 2: ch. 1, Honderich 1996). Others, including Richard Double, contend that the incongruity of our ideas and attitudes concerning freedom and moral responsibility are radically irreconcilable, which entails that our conceptions of freedom and responsibility are incoherent. On this view, there is no correct view about or attitudinal response to determinism, if the latter is descriptive of the nature of our world (Double, 1991, Double 1996a-b).

The future direction of reflection on moral responsibility is uncertain. On the one hand, there has been a resurgence of interest in metaphysical treatments of freedom and moral responsibility in recent years, a sign that many philosophers in this area have not been persuaded by Strawson's central critique of such treatments. On the other hand, the interpretations and further development of Strawson's work have

increased in both their significance and influence. What is clear is that the long-standing interest in understanding the concept of moral responsibility and its application shows no sign of abating.

Stanford Encyclopedia of Philosophy
Notes to Moral Responsibility

Notes

[1.] In an effort to streamline the following discussion, I have chosen to restrict my focus to morally significant actions (and possibly other items--e.g., traits--subject to moral evaluation) and have assumed that moral responsibility involves both positive and negative reactions like praise and blame. In doing so, I set aside two important ways of understanding the notion of responsibility, advocates of which might object to these introductory remarks. First, some think that the scope of responsibility is not restricted to actions (and other items) subject to moral evaluation but in principle applies to all intentional actions (as well as other items that may be linked to such actions. See e.g., Fischer and Ravizza, 1988, ch. 1; and Haji, ch. 1). Second, some contend that the idea of moral responsibility, properly explicated, involves reference to forms of blame alone (see e.g., R. J. Wallace, p. 12).

[2.] For further discussion of various kinds of responsibility, see Hart, ch. 9; and Feinberg, pp. 130-139.

[3.] The term, ‘person,’ is here being used as a technical term. This is important to realize because it is an open question whether the class of persons is co-extensive with the class of human beings. This may be either because there are (or someday may be) persons who are not human beings or because not all human beings qualify as persons in the relevant restricted sense.

[4.] For discussion of a challenge to this claim, see Williams, ch. 2-3.

[5.] Curren and Roberts have challenged the traditional view that Aristotle was discussing a conception of moral responsibility similar to our own. For a noteworthy defense of the traditional view in the face of such challenges, see Meyer, 1993, chs. 1-2.

[6.] This way of dividing control and epistemic conditions on responsibility continues to be influential. For excellent treatments of Aristotle's account, see Broadie, ch.3; Everson, 1990; Irwin, 1980; Meyer, 1993; and Roberts.

[7.] The ambiguity displayed in Aristotle's conception of moral responsibility is linked to another—how to interpret the condition that the action or trait be *up to the agent*. Some believe that the action (or trait) needs to be up to the agent in the sense that she could have, at the time of action (or development of the trait), either performed it or not performed it (or developed it vs. not developed it). Others believe the action or trait need be up to the agent only in the sense that it follows from the agent's desires/emotions/beliefs in such a way that had she decided otherwise, she would have done or been

otherwise. Those who adopt the former reading of Aristotle's account adopt the merit reading of Aristotle's conception of responsibility while the latter often adopt the consequentialist reading.

[8.] Until recently, this classification was parasitic upon and parallel to a more fundamental distinction between 1) those who believed that it could not both be true that persons sometimes acted freely and that persons were causally determined; and 2) those who believed both could be true. That is, acting freely—in the sense of being able to do otherwise--was assumed to be a precondition of being morally responsible for an action, so one's view of the compatibility of freedom and determinism was thought to entail one's view about the compatibility of moral responsibility and determinism. These assumptions have been called into question in recent years (see Frankfurt), opening up the possibility of views which are incompatibilist in one sense but compatibilist in another (see Fischer, 1994, 178-183). This recent wrinkle is ignored in the text for ease of exposition.

[9.] A contemporary example of this general way of thinking is a version of the merit view that has come to be dubbed, the ‘ledger view’ because of its reliance on the metaphor of a ledger, or report card. According to the ledger view, credit and debit entries are made on one's ledger on the basis of how one conducts one's life. Holding a person responsible is understood centrally in terms of a judgment that he or she has such a credit or debit. The associated attitudes, feelings, and their outward expression are byproducts of this judgment. These judgments are justified—i.e., the agent is praiseworthy or blameworthy for the existence of the credit or debit—when and only when the objective conditions on being responsible are met. On this view, then, particular judgments about an agent's responsibility can be justified only if there is reason to think that agents, in general, can meet such objective conditions. In other words, particular judgments rest upon the judgment that the practice of holding responsible can be rationally defended against possible defeaters (e.g., causal determinism). For examples of the ledger view, see Glover 1970, p. 64; Feinberg 1970, pp. 30-31; and Zimmerman 1988, pp. 38-39. For helpful discussions of the view, see Watson 1987, p. 262; Fischer and Ravizza 1993, pp. 16-17; and Fischer and Ravizza, 1998, pp. 8-10, nt. 12.

[10.] For helpful discussions of Strawson's view, see Bennett; Watson, 1987; Russell; Fischer and Ravizza, 1993, pp. 14-22; R. Jay Wallace; Magill, pp.19-22; and McKenna.

[11.] Note how this addresses one of the concerns motivating reflection on moral responsibility (see introduction). If Strawson is correct, then his view helps to explain one reason why persons are unique--namely, only they can be proper recipients of the reactive attitudes.

[12.] A more particular criticism of Strawson's aimed at consequentialist interpretations of the concept of responsibility has also been influential. This criticism follows from his account of the kind of attitudes involved in holding someone morally responsible and is nicely captured by Jonathan Bennett: "Displays of indignation or of gratitude often produce good results: but such feelings cannot be motivated by the desire to produce good results, nor, it seems, are we able closely to control them by thoughts of what will bring best results (p. 22)." In other words, Strawson denies that our practice of holding responsible is being driven by a desire to bring about good results and a judgment that our reacting in certain ways will

bring about that result (and/or that we could comprehensively adjust our reactions in accordance with such a goal), as the traditional consequentialist view seems to suggest. To be preoccupied with the goal of achieving the best results is to regard the candidate as an object of manipulation or treatment, a stance which precludes the participant reactive attitudes altogether. According to Strawson, any view that fails to acknowledge the essential role of the reactive attitudes within the participant perspective can no longer claim to be an account of *moral* responsibility, as we know it. (P. F. Strawson, 20-21). Others, building on Strawson's account, have argued that the consequentialist account also fails to capture the inherent backward-looking focus of the reactive attitudes (e.g., they are often reactions to what someone has *done*), focusing as they do on the achievement of some future goal (see Bennett, p. 37 and R. Jay Wallace, pp. 56-58). To criticisms of this kind, some consequentialists have argued that one must not confuse the intentions of the person engaged in the practice of holding responsible with the function of the overall practice. On this view, the consequentialist account is aimed at describing and justifying the function of holding a person responsible, not the intentions involved in doing so (see e.g., Kupperman, 60-64).

[13.] There are interesting parallels here with Gary Watson's "Two Faces of Responsibility", wherein Watson argues that there are two aspects to our concept of moral responsibility—one concerned with whether an action is attributable to an agent and another focusing on whether the agent is accountable for the action. But Watson does not go so far as to suggest that either of these aspects entails incompatibilism or compatibilism.

Medieval Theories of Relations

The purpose of this entry is to provide a systematic introduction to medieval views concerning the nature and ontological status of relations. Given the current state of our knowledge of medieval philosophy, especially with regard to relations, it is not possible to provide a detailed survey of the views of even the most important medieval philosophers. In what follows, therefore, I shall restrict my discussion to identifying and describing (a) the main types of position that were developed during the Middle Ages, and (b) the most important historical and dialectical considerations that shaped their development. Along the way, however, I will have occasion to examine in detail certain aspects of the views developed by important representatives of all the main medieval positions, including Peter Abelard (1079-1142), Gilbert of Poitiers (1085-1154), Albert the Great, (1200-1280), Thomas Aquinas (1225-1274), John Duns Scotus (1265-1308), Henry Harclay (1270-1317), Peter Aureoli (1280-1322), and William Ockham (1285-1347).

Introduction

It will be useful to begin this entry with a general introduction to the medieval discussion of relations, highlighting some of the main historical developments to be treated at more length in subsequent sections.

All theorizing about relations in the Middle Ages begins with Aristotle's short treatise, the *Categories*. Due to historical circumstances, this Aristotelian text was one of the very few pieces of ancient Greek philosophy available in the Latin west between the seventh and twelfth centuries, and the only one to contain a systematic philosophical treatment of relations. In the *Categories*, Aristotle identifies relations as one of the ten highest kinds or categories, one of the so-called *summa genera*, and he devotes an entire chapter -- the seventh chapter of the treatise -- to distinguishing the members of this category from those of the other categories (most notably, substance, quantity, and quality).[1] On the standard medieval interpretation of this chapter, Aristotle is attempting to distinguish relations at least partly on the basis of semantic or logical considerations -- that is, on the basis of the differences between statements containing relational (or 'relative') terms and those containing only non-relational (or 'absolute') terms. This approach to characterizing relations helps to shape the way medieval philosophers understand them, and, as we shall see, it gives rise to a common medieval distinction between things that qualify as relations merely according to speech (*relationes secundum dici*) and things that qualify as relations in accordance with their nature or being (*relationes secundum esse*).

In addition to discussing the proper characterization of relations, Aristotle also suggests in the *Categories* a general model or paradigm for analyzing relational situations. According to this analysis, whenever two substances are related, what relates them is a pair of monadic properties or accidents. Thus, if Socrates is similar to Theaetetus (i.e., resembles him with respect to some quality)[2], this is not to be explained by an entity to which Socrates and Theaetetus are somehow jointly attached (namely, the dyadic or two-place property, *being-similar-to*). Rather, it is to be explained by a pair of monadic properties or accidents, one of which inheres in Socrates and relates him to Theaetetus, and the other of which inheres in Theaetetus and relates him to Socrates.[3]

This Aristotelian analysis exercises enormous influence during the Middle Ages, and until at least the fourteenth century, medieval philosophers develop their own analysis of relational situations in terms of it. In the context of this analysis the most important debate that arises concerns the precise nature of the properties or accidents that relate particular substances. Some philosophers, such as Peter Abelard and William Ockham, adopt a form of reductivism, according to which the properties in question are accidents falling under categories other than relation. Thus, according to Abelard and Ockham, when Socrates is similar to Theaetetus, this is to be explained in terms of particular qualities, say, their respective colors. Other philosophers, however, such as Albert the Great and John Duns Scotus, reject this form of reductivism, maintaining instead that relations are accidents of a *sui generis* type. Thus, according to Albert and Scotus, when Socrates is similar to Theaetetus, this is to be explained not by their respective colors, but by a pair of accidents whose members are distinct from, and irreducible to, these colors.

Although the analysis of relational situations that Aristotle suggests in the *Categories* appears to be perfectly general, it is clear from his later writings that he does not think all relational situations conform to it. Thus, in the *Metaphysics* he claims that there are relational situations, such as Simmias's thinking about Socrates, in which two substances are related not by virtue of a *pair* of accidents, but in virtue of a single accident possessed by only one of them. Thus, he says "the object of thought [say, Socrates] is said to be related because something else [say, Simmias] is related to it."[4] Some relational situations, in other words, are grounded in a single property or accident of a single *relatum*.

As is well known, Aristotle's *Metaphysics* did not become available to philosophers in the Latin west until the mid-twelfth century, and it did not circulate widely before the thirteenth. Nonetheless, medieval philosophers were independently motivated -- largely on the basis of theological considerations -- to allow for relational situations that fail to conform to the paradigm suggested in the *Categories*. Thus, on the basis of considerations having to do with the doctrine of creation, they were led to acknowledge the existence of situations in which two substances are related by a single property or accident. Similarly, on the basis of considerations having to do with the Christian doctrine of the Trinity, they were led to admit relational situations in which substances themselves qualify as relations.[5] Prior to the fourteenth century, however, relational situations such as these are regarded by most philosophers as special cases or exceptions to the general rule. Indeed, philosophers from this period work hard to make even these sorts of cases conform, at least to some extent, to the paradigm of the *Categories*. This effort, as we shall see, helps to explain the pervasiveness in medieval philosophy of the distinction between the so-called real relations (*relationes reales*) and relations of reason (*relationes rationis*).

The fourteenth century marks an important turning point in the medieval discussion of relations. After this point, there is a noticeable shift away from the Aristotelian paradigm, with the result that many philosophers come to regard those situations in which substances are related by virtue of their accidents as the exception rather than the rule. Part of the explanation is due, perhaps, to a gradual waning of Aristotle's influence, but part of it is also due to substantive doctrinal changes. By the fourteenth century, for example, it is common to deny the existence of any real distinction between a substance and most of accidents, and consequently, philosophers are increasingly willing to say that substances themselves provide the ontological grounding for relational situations. Again, due to important semantic innovations around the same time, and the subsequent emergence of late-medieval nominalism, philosophers begin to depart also from the traditional Aristotelian characterization of relations. Thus, instead of thinking of relations as the items responsible for relating two or more substances, they now begin to think of them as items existing only in the mind -- that is, as mere beings of reason or concepts. With respect to both of these developments, as we shall see, Ockham is an important transitional figure.

2. Aristotelian Background

Although Aristotle discusses relations at various places in his work, his discussion in the *Categories* is the most important for understanding the development of medieval views about relations. Part of the reason, as I have already indicated, is that until the twelfth century, the *Categories* is medieval philosophers' sole direct source for Aristotle's views about relations. But part of the reason is also theoretical in nature: in the

Categories Aristotle develops a basic account of relations that is presupposed by his other discussions. Thus, even when some of these other discussions -- such as those in the *Physics* and *Metaphysics* -- become available, medieval philosophers interpret them in light of their understanding of the *Categories*.

Aristotle's discussion in the *Categories* influences the development of medieval views about relations in several ways. First of all, it introduces the basic framework and terminology that comes to dominate all medieval theorizing about relations. Second, and perhaps most importantly, it articulates the main claims in response to which medieval philosophers develop their own views. Indeed, as we shall see, medieval views about relations can be distinguished largely by the extent to which they agree with three claims commonly associated with Aristotle's discussion in the *Categories*: (1) relations are the items that relate substances, (2) the items that relate substances are accidents, and (3) no substance is a relation. Finally, the details of Aristotle's discussion in the *Categories*, especially in chapter 7, give rise to a number of important medieval debates, as well as to the traditional distinction between relations merely according to speech (*secundum dici*) vs. relations according to being (*secundum esse*). In order to understand the development of medieval views about relations, therefore, we must begin with some account of Aristotle's discussion in the *Categories*.

2.1 Framework and Terminology of the *Categories*

Throughout the *Categories* Aristotle assumes that relations comprise one of the accidental categories, and hence that they must be understood as items *inhering* in particular substances. This helps to explain why, unlike contemporary philosophers who speak of relations as holding *between* two or more things, Aristotle prefers to say that relations inhere in one thing and somehow point toward (*pros*) another. Indeed, Aristotle's preferred name for relations just is “things toward something” (*ta pros ti*).

During the Middle Ages, it is customary for philosophers to refer to relations using not only Aristotle's term, “toward something” (or *ad aliquid*, the verbatim Latin equivalent of *pros ti*), but two others as well: “relative” (*relativum*) and “relation” (*relatio*). In the early Middle Ages, philosophers often move freely among these terms without paying much attention to their various senses.[6] Over time, however, they come to emphasize their differences, sometimes giving elaborate explanations as to why one of the three terms is more appropriate than the others. To give just one example, consider the following passage by Albert the Great:

> Now the most general genus in the arrangement of this predicable is toward something (*ad aliquid*), or relative (*relativum*), or less properly speaking, relation (*relatio*), as some people say. But it must be recognized that the most general genus is signified most clearly by the name “toward something”, which is a preposition together with [the term] “something” in [the accusative] case. For this name conveys the two things that are in a relative, namely: [i] diversity, which the preposition indicates through its taking an object (*transitionem*), and [ii] the direction of the comparison, which the accusative case indicates when something is called *toward something*.[7]

Whatever their disagreements about the appropriateness of these terms, it was generally agreed that the terms “toward something” and “relative” are related to the term “relation” in the way that a concrete term (such as “white”) is related to its abstract counterpart (such as “whiteness”).

Since “relation” is the term most familiar to us, in what follows I shall rely on it whenever possible. It is important to recognize, however, that medieval philosophers introduce a number of other abstract terms more or less synonymous with “relation” (*relatio*) whose connotations they often regard as more informative than any of those discussed so far. A partial list of such terms includes: “comparison” (*comparatio*), which has psychological overtones, and so is often (though not exclusively) used by conceptualists; “outward-looking-ness” (*respectus*), which draws on a visual metaphor to suggest that relations are that in virtue of which a substance “looks out toward something” (*respicit ad aliquid*); “disposition” (*habitudo*) or “relative disposition” (*habitudo relativa*), which suggests that relations account for the way a thing “holds itself toward something” (*se habere ad aliquid*); and “order” (*ordo*), “ordering” (*ordinatio*), and “directionality” or “toward-ness” (*aditas*), which are used to indicate that relations account for the order or structure we find in the world.

Although Aristotle makes scattered remarks about relations throughout the *Categories*, it is only in chapter 7 that he singles them out for detailed independent consideration. Because the discussion in this chapter is important for understanding the development of the medieval debate, it will be useful to consider how it was commonly understood by philosophers from this period.

2.2 Relations in *Categories* 7

Aristotle's discussion in *Categories* 7 opens rather abruptly with the statement of a particular definition or account of relations. According to this definition, which medieval philosophers attribute to Plato, relations are things spoken of in a certain way. Whether or not this definition is really Plato's, it certainly appears to be well entrenched by Aristotle's time -- as is indicated by the fact that Aristotle says we are at least prepared to *call* something a relation just in case it satisfies the conditions specified by this definition:

> We call the following sorts of things toward something: all those things said to be just what they are *of* or *than* something, or *toward* something in some other way (any other way whatsoever). Thus, what is larger is said to be what it is *than* another (it is said to be larger than something); and a double is said to be just what it is *of* another (it is said to be double of something); similarly with all other such cases.[8]

As the medievals often interpret it, this definition identifies relations in terms of the predicates by means of which they are signified or “spoken of”. Medievals refer to the predicates in question as “relative terms” (*ad aliquid* or *relativa*)[9], and understand them, roughly speaking, as those terms whose true predication requires a comparison to something other than the subject of which they are predicated. Thus, “taller” (*maius*) is a relative term, they say, because when we assert of something that it is “taller” -- that is, when we predicate the term “taller” of it -- we necessarily do so in comparison to something else. We don't say merely that Simmias is taller; we say that he is taller *than* Socrates, or Theaetetus, or the average

man. Similar remarks apply, they say, to “double”. Borrowing on the medievals' behalf the notation of first-order logic, we can make this characterization of relative terms precise by saying that a term *F* is relative just in case a predication of the form “*Fx*” is more perspicuously represented as a predication of the form “*Rxy*”. Medievals refer to a term as *absolute* just in case it is not relative.

As the medievals understand it, therefore, the preliminary definition characterizes relations as the items signified by relative terms -- or what we would nowadays call polyadic or many-place predicates. This characterization seems initially promising, and medieval philosophers often employ it in their writings. In the end, however, they think it must be rejected -- or at least modified. For according to them, not everything we are prepared to *call* a relation actually *is* a relation. In rejecting the first or Platonic definition, the medievals take themselves to be following Aristotle, who rejects the definition on the grounds that it allows certain substances (namely, heads and hands) to qualify as relations. As Aristotle himself says:

> If the [first] definition of things toward something was adequately assigned, then it is exceedingly difficult, or impossible, to reach the conclusion that no substance is toward something. But if, on the other hand, it was not adequately assigned, and things toward something are rather [defined as] *those things for which this is their very being: to be toward another in a certain way*, then perhaps something may be said about the problem [of heads and hands].[10]

In rejecting the first definition of relations, medieval philosophers take Aristotle to be calling our attention to the fact that some relative terms do not signify relations. Terms such as “head” and “hand” clearly count as relative, since statements of the form “*x* is a head” and “*x* is a hand” are more perspicuously represented as of the form “*x* is a head of *y*” and “*x* is a hand of *y*”. Nonetheless, what these terms signify, the medievals say, are not relations but parts of substances. On the basis of these and other such examples, therefore, they conclude that relations must be identified not with the items signified by relative terms, but with a proper subset of them.

Now at this point we are still left with the question of how to identify the members of the relevant subset. Here medieval philosophers think that Aristotle's second definition -- which I have italicized in the passage quoted above -- can be of some help. The purpose of this definition, as it is commonly interpreted, is to provide a characterization of relations in terms of their metaphysical function or role. On this interpretation, relations are the items that actually serve to relate two (or more) things -- that is, the items *in virtue of which* things are related. Read in this way, Aristotle's definition provides a clear explanation for why heads and hands fail to qualify as relations. The items signified by the terms “head” and “hand” do not relate anything. On the contrary, they are things standing in relations.

The distinction between what actually serves to relate (or has the disposition to relate) and what merely stands in some relation is often used by medieval philosophers to explain the difference between the two definitions in *Categories* 7. This understanding of the definitions, moreover, gives rise to the common medieval distinction between things that qualify as relations merely according to speech (*relationes secundum dici*) and things that qualify as relations in accordance with their nature or being (*relationes*

secundum esse), as the following passage from Aquinas's *Summa Theologiae* nicely illustrates:

> Some relative terms -- such as “master” and “slave”, “father” and “son” -- are imposed to signify relative dispositions themselves (*ipsas habitudines relativas*); these terms express things relative *secundum esse*. But other relative terms -- such as “mover” and “moved”, “head” and “headed”, and terms of this sort -- are imposed to signify things on which certain relations follow; these terms express things relative *secundum dici*.[11]

The intuition behind this common distinction is that every relative term must somehow be associated with a relation, otherwise there would be no basis for the comparison involved in its predication. Nonetheless, since only certain relative terms such as “father” and “son” actually signify relations, others such as “head” and “hand” must signify non-relational things *via* their relations (such as being a part or being a whole).

Although medieval philosophers typically agree that there is a distinction to be drawn between relations *secundum dici* and relations *secundum esse*, and that heads and hands and other body parts should be included in the former class, there is often disagreement about which class certain other examples (most notably, knowledge and perception) should be included in. As the medievals recognize, terms such as “knowledge” and “perception” are relative (for statements of the form “*x* is knowledge” or “*x* is a perception” are more perspicuously represented by statements of the form “*x* is knowledge of *y*” and “*x* is a perception of *y*”). They disagree among themselves, however, about whether the items signified by these terms are relations *secundum dici* (i.e., things on which certain relations follow) or relations *secundum esse* (i.e., things which actually serve to relate two or more things). Near the end of *Categories* 7, Aristotle suggests an epistemic criterion for deciding in particular cases whether something qualifies as a genuine relation. But because this criterion is extremely difficult to understand, it does not provide any clear resolution to the original disagreement. Indeed, debate about how to distinguish between relations *secundum esse* and *dici* continues throughout the Middle Ages.

Aristotle ends *Categories* 7 almost as abruptly as he began it. Having indicated his own position, he leaves us with the following cautionary remarks:

> It is perhaps hard to make firm statements on such questions without having examined them many times. Still, to have gone through the various difficulties is not unprofitable.[12]

Medieval philosophers take Aristotle's reticence here as an invitation to refine and improve on his own account of relations and to develop it in their own ways. As Boethius, whose Latin translation is responsible for transmitting these words to the Middle Ages, says in his commentary on this passage of Aristotle:

> He would never have said this if he were not prompting us to further reflection and to even greater exercise of subtlety. Because of his exhortation, we shall not hesitate in the least to raise [further] questions and offer [our own] solutions to them in other places.[13]

3. Relations in Medieval Philosophy

Aristotle's discussion in *Categories* 7, at least as it is understood by his medieval commentators, presupposes a certain view about the nature and ontological status of relations, and hence is not primarily metaphysical in nature but definitional. Thus, Aristotle's discussion begins with the assumption that relations are a certain type of accident, and then proceeds to inquire after their proper characterization, eventually arriving at the view that all and only those accidents that are both signified by a relative term and actually serve to relate their subjects qualify as relations. Medieval philosophers, by contrast, tend to adopt Aristotle's characterization of relations, but not his assumptions about their nature and ontological status. That is to say, they begin with the view that relations are a proper subset of the items signified by relative terms -- namely, all and only those items that actually serve to relate things -- and then proceed to ask about the nature and ontological status of these items, in particular whether in every case they must be identified with an Aristotelian accident.

There are two reasons why medievals think they are entitled to adopt Aristotle's final characterization of relations without also adopting his views about the nature of the entities so characterized. First of all, Aristotle's preferred characterization of relations, as they see it, is ontologically neutral. Although it may be tempting, within a substance-accident framework, to assume that only accidents can both be signified by relative terms and relate substances, they think there is no reason in principle why a substance cannot also play these roles. Secondly, and perhaps more importantly, the medievals think there are at least some cases in which relations cannot be identified with accidents. The most common examples are, of course, theological in nature. On the Christian view of the Trinity, for example, the divine persons stand in various relations, both to one another and to things distinct from God. Nonetheless, the medievals argue, there are no accidents in God. In order to accommodate cases such as these, therefore, the medievals think that Aristotle's account must be extended to allow for relations that are not accidents.

3.1 The Rejection of Polyadic Properties

Most medieval philosophers, therefore, think they can accept Aristotle's second definition of relations without begging any substantive metaphysical questions as to their nature or ontological status. And this in turn allows for the possibility of identifying relations in different situations with entities of different ontological types. Before turning to the different types of entity with which medieval philosophers actually identify relations, it is worth noting that there is at least one type of entity with which they think relations can never be identifed, namely, the type we would nowadays refer to as *polyadic* or *many-place property*. Despite their differences, medieval philosophers appear to be unanimously agreed that no entities of this type exist in extramental reality.

Historians of philosophy sometimes speak as if medievals lacked the very concept of a polyadic property -- indeed as if this concept only became possible in the nineteenth and twentieth centuries with the advent of a formal logic of relations and multiple quantification.[14] But this is surely mistaken. What advances in formal logic have made possible is not the concept of a polyadic property, but merely its representation

within a formal system. And in any case, we have already seen that the notion of a polyadic predicate, from which our own concept of a polyadic property is derived, has a direct analogue in the medieval notion of a relative term.

There is, moreover, explicit textual evidence to support the claim that the medievals conceived of relations as polyadic properties. Medieval philosophers often compare relations to a road (*via*) that runs between two cities, or to a palisade running between two watchtowers (*inter-vallum*).[15] In drawing these sorts of analogies, medieval philosophers take themselves merely to be developing a suggestion of Aristotle's in the *Physics*.[16] By the time of Peter Aureoli (d. 1322), however, reference to Aristotle (or indeed any authority) for conceiving of relations in this way comes to seem almost otiose. As Aureoli himself says at one point:

> In the third book of his commentary on the *Physics*, comment twenty, the Commentator [= Averroes] says that a relation is a disposition (*dispositio*) existing between two things. But even apart from him it is clear that fatherhood is conceived of as if it were a kind of medium connecting a father with his son. And the same is true of other relations.[17]

This passage makes it clear that the standard way of conceiving of relations is as polyadic entities.

Despite the fact that medieval philosophers conceive of relations in this way, they explicitly deny that anything in extramental reality exactly corresponds to this conception. Returning to the passage from Aureoli, we can see that, immediately after pointing out that relations are conceived of as a sort of 'interval' (*intervallum*), he goes on to deny the existence of any such intervals in extramental reality:

> It appears that a single thing that must be imagined as some sort of interval (*intervallum*) existing between two things cannot exist in extramental reality, but only in the intellect. [This appears to be the case] not only because nature does not produce such intervals, but also because a medium or interval of this sort does not appear to be in either of the two things [it relates] as in a subject, but rather between them where it is clear that there is nothing which can serve as its subject.[18]

As this passage from Aureoli makes clear, the root of the medievals' objection to polyadic properties is ontological in nature, and has to do with the relationship of subjects to their attributes. From Aristotle, the medievals inherit a division of real beings into substances and accidents, and they typically take this division to be both exclusive and exhaustive (since it is given in terms of a contradictory pair of properties, namely, being in a subject vs. not being in a subject).[19] Like Aristotle, moreover, the medievals think of individual substances as the primary subjects of predication and divide their attributes into two main kinds, essential and accidental. Now in the case of individual substances, it is perhaps clear that they are not polyadic in nature. But medievals think the same is also true of their attributes. For attributes, as they see it, are to be conceived of as constituents, or in a broad sense as 'parts' of substances, and hence as incapable of belonging to more than one substance at a time. In the case of essential attributes, they think this is so obvious as to barely merit mentioning in the context of relations.[20] But

they are fond of pointing this out in the case of accidents. To take just one particularly striking example, consider how Aquinas responds in his *Sentences* commentary to the question whether it is possible for "numerically one and the same relation" to belong to belong to two subjects at a time: "This cannot be, for one accident cannot belong to two subjects".[21]

Although the medieval objection to polyadic properties stems in large part from ontological considerations, medieval philosophers also offer other reasons for rejecting them. Sometimes the reasons are grounded in an appeal to theoretical parsimony: all other things being equal, the ontology that postulates the fewest types of entity is to be preferred. Thus, as Ockham is so fond of saying: "It is futile to do with more [entities] what can be done with fewer".[22] Again, the reasons are sometimes grounded in phenomenological or epistemological considerations: we are not presented in experience with anything but individuals and their so-called absolute attributes -- that is, substances and their quantities and qualities. Albert the Great, for example, mentions this sort of objection and traces it to certain Muslim philosophers: "Some fairly recent philosophers such as Avicenna and Alfarabi . . . say that no form that is a being (*ens*) belongs to a thing unless it is absolute as far the being (*esse*) it has in itself is concerned -- as is clear from looking at cases of what is hot, cold, white, black, and *all other things*."[23]

3.2 Anti-Realism about Relations

The rejection of polyadic properties might seem to commit one to a form of anti-realism about relations. This was, in fact, the position of Peter Aureoli. If there are no polyadic properties or 'intervals', he argues, then there is nothing in extramental reality to correspond to our relational concepts. Reasoning from the common medieval assumption that relations are items corresponding to our relational concepts, he concludes that "a relation cannot be posited except in apprehension alone".[24] Thus, relations do exist, on his view, but only as the contents of certain concepts or apprehensions -- or as what he elsewhere describes as beings of reason (*entia rationis*). Strictly speaking, therefore, Aureoli does not want to deny that things can be related, but only that they can be related apart from the activity of the mind.

Given the current state of medieval research, it is difficult to know how widespread this (or any other) form of anti-realism was during the Middle Ages. Shortly after Aureoli's death, certain aspects of his conceptualism appear to have met with considerable success. Ockham and his followers, for example, accept Aureoli's view that relations are concepts or beings of reason, though unlike Aureoli, as we shall see, they think this is compatible with saying that things are related independently of the activity of the mind. And one can find echoes of the same sorts of view throughout the writings of early modern philosophers.[25] Prior to the fourteenth century, however, it is difficult to identify any unambiguous representatives of anti-realism, at least in the Latin west. Albert the Great claims to find something akin to Aureoli's argument in the writings of Alfarabi (d. 950) and Avicenna (d. 1037), but he does not say whether either of these figures endorses the argument or merely presents it for consideration.[26] Again, Aquinas suggests that a similar view can be found in the writings of Gilbert of Poitiers and his followers, the so-called Porretani, but the suggestion is controversial, and in any case Aquinas reports that Gilbert later retracted the view in the face of theological controversy.[27] Unless further research alters the current picture, therefore, it would appear that, although anti-realism may have had something of a foothold in the

Arabic speaking world, most notably among the members of a group of orthodox Muslim theologians known as the Mutakallim•n, in its more radical forms it was always a minority position in the Latin west.[28]

3.3 Realism without Polyadic Properties

Thus, if we take anti-realism to be the view that (a) nothing in extramental reality corresponds to our relational concepts and (b) nothing is related independently of the activity of the mind, it appears that most medieval philosophers would reject it. Nor is it hard to see why. Like most of us, the medievals recognize the implausibility of saying that facts like Simmias's being taller than Socrates are somehow dependent on the activity of the mind.[29] Indeed, they often argue that such an anti-realist view about relations cannot account for even such basic facts as the real structure of the universe, the existence of real composition, causality, spatial proximity, or even the objectivity of mathematical knowledge. Thus, Ockham speaks for the majority when he asserts in his *Ordinatio*:

> The intellect does nothing to bring it about that the universe is one, or that a whole is composed [of its parts], or that causes in spatial proximity [to their effects actually] cause [their effects], or that a triangle has three [angles], etc. . . .any more than [the intellect] brings it about that Socrates is white or that fire is hot or water cold.[30]

Again, realism about relations seems to be implied by a standard medieval interpretation of the Aristotelian categories. "For nothing is placed in a category" says Aquinas "unless it is something existing outside the soul".[31] Thus, if realism is false, there should not even be a category of relation

In addition to philosophical objections to anti-realism, medieval philosophers also had theological grounds for opposing it. Christian doctrines such as the Trinity were often thought to require realism about certain theological relations. Indeed, the existence of real relations in God is affirmed at the Council of Rheims in 1148, and shortly thereafter it becomes customary to say that the denial of this entails a form of heresy known as Sabellianism.[32]

But if there is general consensus among medieval philosophers that anti-realism ought to be rejected in favor of what we might call *realism without polyadic properties*, what is to be said about arguments such Aureoli's, which in effect deny the possibility of relations without polyadic properties? Here I think it is useful to consider the reply given by Albert the Great. Although he writes a generation before Aureoli, he explicitly addresses this sort of argument, and the reply he offers appears to be perfectly standard. According to Albert, the problem with arguments of this type is that they rely on the assumption that *if there are no polyadic forms or properties, then there is nothing in extramental reality corresponding to our relational concepts*. This assumption would be true, he suggests, only if our conceptual framework displayed an exact isomorphism to the structure of the world. But as Albert sees it, there is no reason in principle why a polyadic concept should not have something non-polyadic in extramental reality corresponding to it.[33] In making this sort of reply, Albert aligns himself with a medieval tradition of rejecting the view that *for every distinct type of concept there is a distinct type of entity*. This view is often

associated in medieval philosophy with Plato and his followers, and by the time of Ockham it is regarded, perhaps somewhat hyperbolically, as the source or root (*radix*) of the greatest errors in philosophy. As Ockham himself says at one point: "to multiply beings according to the multiplicity of terms . . . is erroneous and leads far away from the truth".[34]

For most medieval philosophers, therefore, the question is not *whether* there are any things in extramental reality corresponding to our relational concepts, but *what* these things are in themselves. But having ruled out the possibility of their being polyadic in nature, the medievals are not left with many options. Because they accept a form of realism, they are committed to saying that, at least in many cases, there is something in extramental reality grounding these concepts. But because they also accept a form of realism without polyadic properties, and are committed to a broadly Aristotelian ontology, they have no choice but to identify these extramental grounds with either individual substances or their monadic properties (whether they be accidental or essential).

Throughout the medieval period philosophers are attracted to the view that Aristotle suggests in the *Categories*, namely, that relations (or the items grounding our relational concepts) are accidents. For reasons I have already mentioned, no medieval can allow this account to hold for all relations, since there are cases, especially theological ones, in which involve relations but no accidents. Nonetheless, until the fourteenth century, this account is taken to apply so widely that there emerges a kind of paradigmatic analysis of relational situations. According to this analysis, if a judgment of the form '*aRb*' is true, what makes it true is a pair of individuals, *a* and *b*, and a pair of accidents, *F* and *G*. Thus, if it is true that Simmias is taller than Socrates, this is to be explained by a pair of monadic properties, one of which inheres in Simmias and relates him to Socrates as taller and the other of which inheres in Socrates and relates him to Simmias as shorter. According to this analysis, moreover, it is the particular accidents that correspond to, and thus ground, relational concepts such as 'taller than' and 'shorter than'.

As we shall see in the next section, it is within the context of this paradigmatic analysis of relational situations that one of the most hotly disputed and intractable debates of all the Middle Ages arises. In order to facilitate my discussion of this debate, I shall hereafter refer to situations that conform to this analysis as *paradigmatic relational situations* and to the pairs of properties or accidents involved in them as *paradigmatic relations*.

4. Paradigmatic Relational Situations

Before turning to the details of this debate, it is worth emphasizing that most medieval philosophers, at least those living prior to the fourteenth century, regard what I have been calling the paradigmatic analysis of relational situations as the analysis provided by Aristotle's discussion in the *Categories*. Aristotle does not explicitly speak of relations there as items corresponding to relational concepts, though this way of speaking would seem to be justified on the basis of his semantic characterization. Nonetheless, he does explicitly identify relations in the *Categories* with accidents and speaks of them as if they always come in pairs. Indeed, as Boethius points out in his commentary, whenever Aristotle refers to the category of relations he refers to it in the plural ("things toward something"), thereby departing from his usual

practice of referring to categories in the singular (“substance”, “quantity”, “quality”, etc.). According to Boethius, Aristotle speaks of the category in this way because its members are unique among categorial beings in that they cannot be understood to exist by themselves:

> Things toward something [i.e., relations] cannot be grasped by the intellect by themselves or individually, so that we could say that things toward something exist individually. Whatever is known regarding the nature of a relation must be considered together with something else. For example, when I speak of a master, this by itself means nothing if there is no slave. The naming of one relative immediately brings with it another thing toward something.[35]

Following Boethius, medieval commentators often take Aristotle's use of the plural to indicate that the category of relations is comprised by pairs of correlatives or converse relational accidents.[36] Simmias cannot be taller than Socrates unless Socrates is shorter than Simmias. Thus, if Simmias is taller than Socrates, it appears that a pair of accidents is needed to explain the situation, one of which is identified with Simmias's tallness (and hence corresponds to the concept ‘taller than’) and the other of which is identified with Socrates's shortness (and hence corresponds to the concept ‘shorter than’).

As the medievals recognize, there are a number of questions that arise about the precise nature and ontological status of these paradigmatic relations. What sort of monadic properties or accidents are they, and how are we to think of them? As the medievals see it, there are two main positions one can take. For convenience, I shall label them, respectively, *reductive* and *non-reductive realism (without polyadic properties*).

According to reductive realism, which is the simplest or most ontologically parsimonious form of realism without polyadic properties, paradigmatic relations are to be identified with ordinary, non-relational accidents -- that is to say, with accidents that fall under Aristotelian categories other than relation. Thus, if Simmias is taller than Socrates, the reductive realist will explain this by appealing to their respective heights, which fall under the category of quantity. Again, if Simmias is similar to Socrates (i.e., resembles him in color, say), the reductive realist will explain this by appealing to Simmias's and Socrates's particular colors, which fall under the category of quality. And so on for other paradigmatic relations.

According to non-reductive realism, by contrast, these relations are to be identified not with ordinary, non-relational accidents, but rather with accidents of a *sui generis* type. Thus, if Simmias is taller than Socrates, this is to be explained by appealing to a pair of *sui generis* accidents that are distinct from, but nonetheless necessitated by, Simmias's and Socrates's heights. Again, the accidents relating Simmias and Socrates as similar are not their colors, according to the non-reductive realist, but a pair of *sui generis* accidents necessitated by them. And so on for the relations involved in other paradigmatic relational situations.

In the medieval discussion of relations, it is this difference -- the difference between reductive and non-reductive realism -- that constitutes the greatest divide among philosophers, and representatives of both

positions can be found throughout the medieval period. Peter Abelard (d. 1142) and Albert the Great (d. 1280) are, perhaps, the best representatives of reductive and non-reductive realism (respectively) in the early and high Middle Ages, whereas William Ockham (d. 1347) and John Duns Scotus (d. 1308) are among the best known examples of these positions in the later Middle Ages. Again, some philosophers appear to have held different positions at different stages of their career. Henry Harclay (d. 1317), for example, began his career as a staunch defender of Scotus's non-reductive realism, but by the end of it gravitated towards a position that is much closer to, and in many ways anticipates, Ockham's specific form of reductive realism.[37]

Beginning in the mid-thirteenth century, the debate between reductive and non-reductive realists is often carried out in the context of the discussion whether relations are identical to their foundations. (This is the context, for example, in which Scotus and Ockham develop their positions.) By the mid-thirteenth century, moreover, it is customary to admit at least a conceptual distinction between relations (such as Simmias's tallness and Socrates's shortness) and the non-relational accidents in virtue of which these relations hold (such as Simmias's and Socrates's heights). The relevant non-relational accidents, in turn, are referred to as foundations or grounds (*fundamenta*) of relations, since their possession is thought to necessitate the holding of relations. In this context, therefore, the important question is whether the distinction between relations and their foundations is *merely* conceptual.

We might expect that reductive realists would always answer this question in the affirmative, whereas non-reductive realists would always answer it in the negative. It turns out, however, this is not the case. For reasons to be explained below, there are some reductive realists who, in spite of rejecting that relations comprise a *sui generis* type of monadic property, nonetheless maintain that relations are in an important sense distinct from their foundations. In light of this complication, I shall continue to cast the medieval debate about the nature paradigmatic relations in terms of reductive and non-reductive realism rather than in terms of the identity or distinctness of relations and their foundations.

4.1 Reductive Realism without Polyadic Properties

As I mentioned above, on the simplest or most ontologically parsimonious form of realism without polyadic properties, what I am calling *reductive realism*, paradigmatic relations are identified with ordinary, non-relational monadic properties or accidents. Now we might expect this form of realism to appeal to anyone committed to realism without polyadic properties. After all, failure to reduce such relations to such accidents threatens to make them mysterious. If paradigmatic relations are monadic properties, but not ordinary, non-relational accidents, then how are we to understand them? On this count, however, the position of the reductive realist is perfectly intelligible. According to it, if Simmias is taller than Socrates, the holding of the relation will be explained by the possession of a pair of ordinary heights -- say, being-six-feet-tall in the case of Simmias and being-five-feet-ten-inches-tall in the case of Socrates.

These sorts of considerations certainly play a role in the debate between medieval reductive and non-reductive realists. As we shall see, non-reductive realists typically recognize that the chief difficulty for their view lies in providing a principled motivation for, and then explaining the precise nature of, the *sui*

generis monadic properties that they identify with relations. Reductive realists, by contrast, often rely on considerations of theoretical parsimony to motivate their own views. This is certainly true in the case of Abelard and Ockham, whom I earlier identified as reductive realists. In the case of Abelard, these considerations are not explicitly formulated, though they are part-and-parcel of his general approach to metaphysics and philosophy of language.[38] In the case of Ockham, the appeal to parsimony is much more explicit, often taking the form of what has come to be known as Ockham's razor: “Plurality should not be assumed without necessity”.[39]

Another consideration that plays an important role in the debate between reductive and non-reductive realists has to do with the proper interpretation of authoritative texts. Since medieval philosophers develop their theories of relations in the course of reflecting on Aristotle's *Categories*, they often present their views as the one actually suggested by the text itself. This is especially true in the early Middle Ages. Abelard, for example, suggests that his reductive theory is a direct consequence of Aristotle's second definition of relations. Thus, when Aristotle characterizes relations in *Categories* 7 as “those things for which this is their very being: being toward something in a certain way”, Abelard argues that this should be interpreted to mean that relations are items that *make other things to be relative or related* -- that is to say, that they are what we might call relative-making characteristics.[40] Textual considerations and direct appeals to Aristotle's authority play a much bigger role in early medieval debates than they do in the high and later Middle Ages, when literal commentary was no longer the dominant form of philosophical literature. Nonetheless, these sorts of considerations continue to be important throughout the Middle Ages. Even Ockham, in his *Summa logicae*, addresses the issue of whether Aristotle should be interpreted as holding some form of non-reductive realism. “There are many theologians of this opinion,” he says “and at one time even I believed it to have been Aristotle's opinion. Now, however, it seems to me that the contrary opinion follows from his principles.”[41]

One final argument used by reductive realists to motivate their position is worth mentioning here. This argument has to do with the nature of relational change. Almost all medievals accept the intuitively plausible view that things can acquire (and lose) relations without undergoing any real (as opposed to what is nowadays called a merely Cambridge) change. Thus, when Simmias comes to be taller than Socrates, Socrates acquires the relation of being shorter than Simmias. But it would seem that Socrates can acquire this relation without undergoing any real change in himself (say, if he acquires it solely in virtue of a change in Simmias's height).[42] As reductive realists such as Ockham often point out, this fact about relational change admits of a ready explanation on their position.[43] For according to the reductive realist, Socrates's relation of being shorter is nothing over and above Simmias's and Socrates's heights, the latter of which remains unaltered. The same fact, however, appears to pose a serious challenge for the non-reductive realist. For if Socrates's relation is something distinct from Simmias's and Socrates's heights, then apparently Socrates acquires something when Simmias's height increases. But then, contrary to the original intuition, the non-reductive realist must say that Socrates undergoes a real change after all.

These considerations are not the only ones that reductive realists appeal to, but they are among the most important for understanding their position, and I shall rely on them in what follows to motivate and clarify the alternative position of the non-reductive realists.[44]

Before leaving the topic of reductive realism, however, I need to take account of a slight complication. In my discussion to this point, I have allowed myself to speak as if reductive realists intend to identify individual paradigmatic relations such as tallness or shortness with pairs of monadic properties *taken jointly*. I have done this because, at least initially, this seems to be the most natural way to make sense of their position. After all, it is not Simmias's height taken by itself that necessitates his being taller than anyone. On the contrary, it is only when his height is taken together with that of another, say Socrates's, that the relation comes to hold of him. But even if this seems initially to be the most natural way to construe reductive realism, it is not the way medieval philosophers typically understand it.[45] As I indicated earlier, medieval philosophers typically identify relations such as tallness or shortness, not with pairs of monadic properties taken jointly, but with the individual members of such pairs. Thus, even if a pair of monadic properties is required to explain a relational situation such as Simmias's being taller than Socrates, medieval philosophers typically want to say that only one of these properties is to be identified with Simmias's tallness (and hence to correspond to the concept 'taller than'), whereas the other is to be identified with Socrates's shortness (and hence to correspond to the concept 'shorter than'). But how is this possible, especially if the properties in question are supposed to be just ordinary heights?

To begin, let us note that medievals do recognize the worry associated with identifying relations with ordinary monadic properties taken individually. In fact, this recognition sometimes leads them to consider developing reductive realism in just the way suggested above. Thus, in a particularly striking passage from one of Henry Harclay's later works it is suggested that, although the similarity between two white things cannot plausibly be identified with the whiteness of either one, it might nonetheless be identified with the pair of whitenesses taken jointly. Indeed, he even draws on common medieval views about number to make the suggestion plausible:

> A relation is clearly a reality distinct from one foundation, but not a reality distinct from both foundations. For when one white thing [such as Simmias] is posited and then another white thing [such as Socrates] is posited, there is a relation beginning at that point. Thus, the similarity is not a [single] whiteness, but two whitenesses existing at once. Indeed, the two whitenesses can be sufficient to constitute a single species in the genus of relation. Just as two discrete unities of whatever magnitude are sufficient for producing a single species of number, so too the same thing holds for the case at hand. Again, just as plurality or multitude is not a reality different from the constituents of the plurality or multitude, neither is the similarity [of the white things] different [from their whitenesses].[46]

As this passage clearly indicates, medieval philosophers do consider the possibility of identifying relations with pairs of monadic properties or accidents. Having considered this sort of identification, however, they do not typically endorse it. Thus Harclay, who certainly seems to be attracted to a form of reductive realism, proceeds immediately to reject such an identification on the grounds that it would lead to certain absurdities. Citing Avicenna as his authority, he says:

> Avicenna argues against this on the basis of relations involving inferiority and superiority, for it is clearer in those cases than it is for other relations, such as those involving equals.

> For fatherhood is in the father alone and not in the son . . . and the same thing holds of sonship. Therefore one must hold that there are two relations [here]. And in this case it is clear that the relation is not the same reality as [the two] foundations because the relation is not in everything in which the foundation of the *relatum* is. This is the case, too, for relations involving equals, even if it is not as clear.[47]

In this passage, Harclay calls our attention to one of the consequences of identifying relations such as fatherhood and sonship with pairs of properties or accidents. If a relation such as fatherhood just is a pair of accidents, then it would follow that fatherhood is partly in the father and partly in the son (since the pair is such that one of its members inheres in the father, the other in the son). But this, says Harclay, is absurd. Fatherhood is an asymmetrical relation (or as Harclay prefers to put it, a relation involving superiority and inferiority) -- that is to say, if an individual *a* has fatherhood in respect of another individual, *b*, *b* cannot have fatherhood in respect of *a*. Harclay takes this to show that “fatherhood is in the father alone and not in the son”. And the same is true, he thinks, of its converse, sonship, as well as for all other relations, including symmetrical relations or “relations involving equals, even if it is not as clear”.

In this passage, Harclay makes explicit views that appear to be taken for granted by medieval philosophers generally. But if relations are not to be identified with pairs of accidents, how can reductive realists think of them in terms of ordinary, non-relational accidents? After all, the only other option seems to be identifying them with ordinary accidents taken individually -- which as we have seen is problematic. For it is not an ordinary accident such as Simmias's height that necessitates Simmias's being taller, but only this height taken together with that of another. Indeed, it was precisely this point that led us to conclude that “relative-making” is a description best reserved for pairs of ordinary properties taken jointly.

At this point, it seems to me that the reductive realist should respond by saying that, although Simmias's height is not by itself relative-making, it is nonetheless *potentially* relative-making. For if Simmias's height is by itself potentially relative-making, then apparently we are entitled to say that in the presence of another height, such as Socrates's, it becomes *actually* relative-making -- that is to say, it actually comes to relate Simmias to Socrates. This suggests a third option for reductive realists: to maintain that relations are to be identified with ordinary, non-relational accidents *in certain circumstances*.

In fact, it is this last sort of view that I think most reductive realists during the medieval period actually hold. Thus, as I interpret Harclay, this is precisely the view he goes on to develop in the discussion we have been following.[48] Simmias's being taller than Socrates is to be identified, on his view, not with Simmias's height *tout court*, but with Simmias's height in certain circumstances -- including the circumstance that Socrates is five-feet-ten.[49] (One is put in mind here of attempts by certain contemporary philosophers to identify dispositions, such as brittleness or solubility, with their categorical basis in certain circumstances -- namely, the circumstance that the appropriate laws of nature obtain.[50]) To put Harclay's view in a slightly different way, one which will help to bring out its semantic consequences, we might say that in a world in which Simmias exists by himself a judgment of the form ‘Simmias is taller than Socrates’ will be false, and hence nothing will correspond to the relational concept

'taller than'. But in a world in which Simmias is six-feet-tall while Socrates is five-feet-ten, a judgment of the same form will be true, and in this world there will be something corresponding to 'taller', namely, Simmias's height. In such a world, medieval philosophers would say that 'taller' primarily signifies Simmias's height, but indirectly signifies or connotes the height of Socrates.[51]

Now as it turns out, it is not only the reductive realists, but the non-reductive realists as well that speak of relations as accidents of single subjects -- that is, of Simmias's tallness as something belonging only to him, of Socrates's shortness as something belonging only to him, and so on for all other particular relations. In light of what has just been said, therefore, we can clarify our understanding of the paradigmatic analysis of relational situations generally. As indicated earlier, this analysis requires that when a judgment of the form '*aRb*' is true, what makes it true is a pair of individuals, *a* and *b*, and a pair of monadic properties or accidents, *F* and *G*. Reductive realists, as we have just seen, identify *F* and *G* with ordinary categorial accidents, whereas non-reductive realists, as we shall see in the next section, identify *F* and *G* with accidents of a *sui generis* type. But however they construe the nature of these accidents, they both deny that it is the pair of accidents -- that is, *F* and *G* taken jointly -- that corresponds to our relational concepts. On the contrary, they say, *F* directly corresponds to one of our relational concepts, whereas *G* directly corresponds to its converse. Thus, when Simmias is taller than Socrates, reductivists and non-reductivists are agreed that it is an accident of Simmias that directly corresponds to (or as they would prefer to say, is primarily signified by) the concept 'taller than', and an accident of Socrates that is primarily signified by the concept 'shorter than'. To the extent they disagree, therefore, their disagreement concerns only whether the accidents primarily signified by relational concepts can also be signified by ordinary non-relational concepts (and if so, precisely how and under what circumstances).

With these clarifications in mind, I now turn to considerations that lead some medieval philosophers to reject reductive realism in favor of a form of non-reductivism.

4.2 Non-Reductive Realism without Polyadic Properties

Of all the considerations favoring non-reductive realism, perhaps none is more compelling than the intuition that relations have a different nature or 'quiddity' from that of ordinary categorial accidents. As we have seen, medieval philosophers recognize that predications involving relative terms (such as "*x* is taller") are incomplete in a way that monadic or absolute predications (such as "*x* is white") are not. They also recognize, moreover, that unlike absolute terms relative terms come in pairs or sets. Every relative term has a correlative, and the meaning of the one (say, "taller") cannot be understood in isolation from the meaning of the other ("shorter"). These facts about relative terms and predication are often thought to show that the items signified by them have a distinct nature or quiddity from that of their foundations -- the ordinary, absolute accidents. Here again it is useful to quote Harclay:

> Avicenna (*Metaphysics* III, the chapter on relation) says that a relation has its own quiddity distinct from the quiddity of its foundation. Therefore it is a distinct reality. Moreover, in the *Categories* Aristotle says that the being associated with relatives is being-toward-something-else (*ad aliud se habere*). But it is not the case that the being of a foundation is

> being-toward-something-else. Therefore they are not the same."[52]

A reductive realist can, of course, explain the uniqueness of relative terms and predications without introducing relations over and above their foundations. For such a realist can always assert that relative terms are associated with concepts whose content is distinct from that of any non-relational or absolute concepts, and insist that this is all that is required to explain the peculiar nature of relative terms and predications. Even so, there is a question that remains for the reductive realist. Why, it must be asked, if Simmias's being taller than Socrates is nothing ontologically over and above Simmias's and Socrates's heights, do we represent this relation *as if* it were? At this point, it would seem that the reductive realist can only appeal to our psychological make-up. We simply do (or at lest can) represent one and the same situation in two very different ways. As Ockham says in one of his *Quodlibetal* questions, using a slightly different example:

> Socrates is similar to Plato by the very fact that Socrates is white and Plato is white . . . Yet, despite this, the intellect can express these many absolute things by means of concepts in diverse ways: in one way, by means of an absolute concept, as when one says simply 'Socrates is white' or 'Plato is white'; in a second way, by means of a relative concept, as when one says 'Socrates is similar to Plato with respect to whiteness'.[53]

Even if one does not find this sort of appeal to psychology implausible, the non-reductive realist would seem to have a more satisfying reply to the original question -- namely, "Why do we represent Simmias's being taller than Socrates as distinct from Simmias's being six-feet-tall while Socrates is five-feet-ten?" For according to the non-reductive realist, we represent these two situations as distinct because they *are* distinct. Indeed, the non-reductive realist can say that the logical incompleteness of predicates such as "taller" (and its correlative, "shorter") calls our attention to precisely what makes these situations distinct -- namely, the *sui generis* accidents that are possessed by Simmias and Socrates in addition to their respective heights.

Now as most non-reductive realists recognize, there is a difficulty posed by their position -- namely, that of giving a perspicuous account of the nature of paradigmatic relations or relational accidents. They often attribute this difficulty, however, to the fact that the nature in question is *sui generis*. As Albert the Great says, when he turns to the discussion of relations in his commentary on Aristotle's *Metaphysics*: "It is difficult for us to speak about [the category of] *toward something* or relation because it has a nature and being altogether different from the genera of being which have been considered so far [namely, substance, quantity, and quality]."[54] Given that non-reductivists construe the nature of paradigmatic relations as *sui generis*, it is not surprising that they feel the need to resort to metaphors to describe it. Albert himself appeals most often to a visual metaphor of outward-looking-ness (*respectus*), and describes individual relations as that in virtue of which a subject 'looks out toward' (*respicit ad*) another. Other philosophers, however, rely on other metaphors and variously describe the nature of relations as 'directionality' or 'toward-ness' (*aditas*), as a certain kind of disposition or way of holding oneself (*habitudo* or *relativa habitudo*), or again as the principle of 'structure' or 'order' (*ordinatio*).[55]

Of all these metaphors, the ones involving directionality -- or intentionality -- are likely to be the most helpful to us. For there are some contemporary philosophers who characterize intentionality, not in terms of a polyadic or many-place property, but as a *sui generis* type of monadic property.[56] According to these philosophers, intentionality is a property whose intrinsic nature is such that, when it is exemplified by a subject in appropriate circumstances, which include the presence of an appropriate object, it relates its subject to the object in question -- in particular, it relates the subject to it as thinker to object thought. This analogy is useful, I think, because non-reductive realists typically regard intentionality as a special case (or type) of relation. According to non-reductivists, all paradigmatic relations (or at least all those that qualify as *sui generis* accidents) are properties whose intrinsic nature is such that their exemplification in the appropriate circumstances will relate their subjects to something else. It is just that in certain cases, these properties relate their subjects specifically as thinkers to objects thought.

In the end, therefore, it would appear that the non-reductive realists do have something to say in response to the reductivists' worries about the mysterious nature of relations and their appeals to considerations of theoretical parsimony. But what about the phenomenon of relational change? As we have seen, the reductive realists have a natural explanation of it. But is there anything that the non-reductive realists can say about it?

As I said earlier, medieval philosophers share the intuition that the acquisition (or loss) of relations by a subject can occur without any real change taking place on the part of this subject -- that is, solely in virtue of a so-called Cambridge change. To explain this intuition, some non-reductivists think it is enough to say that a relation can be acquired (or lost) without its subject undergoing any real change *with respect to its absolute accidents*. Thus, the example of Socrates's coming to be shorter than Simmias is sometimes glossed by saying that, with respect to absolute accidents, it is true that Socrates comes to be shorter than Simmias solely in virtue of a real change in Simmias. Nonetheless, if we consider Socrates's relative accidents as well, such non-reductivists will say that Socrates has, in fact, undergone a real 'relative' change -- that is, a real change with respect to one of his relations. [57]

But non-reductivists need not take this line. Some, more sympathetic to the reductive realist position on relational change, take cases like that involving Simmias and Socrates as an opportunity to further clarify the nature of relations. Albert the Great, for example, argues that relational accidents are so closely tied to their foundations that they are acquired along with them.[58] Thus, if Socrates comes into existence in a world all by himself at a height of five-feet-ten-inches-tall, he will not only possess a certain quantity (namely, his height), but in virtue of possessing it, he will also possess a *sui generis* relational accident. Now, in such a world, the relational accident will not actually relate Socrates to anyone or anything. In virtue of possessing it, however, he will be *potentially* related. Suppose, however, that Simmias now comes into existence at six-feet-tall. Socrates's relational accident will come actually to relate him to Simmias as shorter. In doing so, however, Albert insists that Socrates will not undergo any real change whatsoever, absolute or otherwise. Not surprisingly this sort of view leads Albert to distinguish sharply between relational accidents and relations (which are just relational accidents in certain circumstances), and to suggests that strictly speaking we should think of the relevant category as comprised, not of relations, but of relational accidents. This, too, helps to explain why in referring to the members of this category Albert prefers the concrete terms "toward something" (*ad aliquid*) and "relative" (*relativum*) to

the abstract term “relation” (*relatio*) -- for relational accidents are ‘toward something’ or outwardly directed even if they are not actually relating their subject to anything.[59]

Like Albert, Aquinas too suggests that there is a close connection between relational accidents and their foundations. Following Albert's terminology, he suggests that in virtue of possessing a specific height or quantity, an individual such as Socrates is *potentially* equal to all those who have the same height, and *potentially* unequal to -- that is, potentially shorter or taller than -- all those with a different height.[60] Like Albert, moreover, Aquinas says that such an individual can come to be *actually* equal (or unequal) to another solely in virtue of a change in that other, and concludes from this that relations must be in their foundations as in a root (*in radice*). [61] On some interpretations, this is to be explained by saying that although relations and their foundations differ formally -- that is, involve different accidental forms or properties -- nonetheless their act of being (*esse*) is identical. Thus, when Socrates comes to be shorter than Simmias as a result of Simmias's growth, Socrates does not undergo a change properly speaking, since he does not acquire any new act of being. Rather, the ‘old’ act of being of his height (sometimes referred to as the ‘*esse-in*’ of the relation) merely acquires a new determination (sometimes referred to as the ‘*esse-ad*’ of the relation), in this case to Simmias.[62]

We have seen enough, I think, to appreciate the main ontological differences that divide reductive and non-reductive realists, and even some of the differences that divide non-reductivists among themselves. As I indicated earlier, in the later Middle Ages these differences tend to emerge in the context of the debate over whether relations are identical with their foundations. As I also indicated, however, we have to be careful not to assume that how a given philosopher answers this question is an infallible guide to his position. For although reductivists typically affirm that relations are identical to their foundations, and non-reductivists typically deny it, there are some reductivists who side, at least verbally, with the non-reductivists on this question. Thus, the later Harclay, as I interpret him, is a reductive realist -- for he not only rejects the existence of *sui generis* relational properties, but also maintains that in paradigmatic relational situations, substances are related by their ordinary, non-relational accidents. Nonetheless, Harclay denies that relations are identical with their foundations, since he thinks this would amount to saying that relations can be straightforwardly identified either with ordinary accidents taken by themselves or with pairs of such accidents taken jointly. Again, as I shall point out in the next section, a number of later medieval reductivists, including Ockham, eventually come to reject the traditional Aristotelian characterization of relations as items that relate substances in favor of the view that relations are items existing only in the mind (as concepts). As we shall see, this does not mean that Ockham and others deny that there are extramental grounds for our relational concepts or even that things can be related by their foundations independently of the mind. On the contrary, it means only that, unlike their predecessors, they refuse to call anything that grounds a relational concept a relation. The fact that these reductivists regard relations as concepts, however, explains why they too are willing to deny the identity of relations and their foundations: for the relevant foundations, according to these philosophers, are ordinary, extramental accidents, and obviously no concept (or act of the mind) could be identical with them.

Finally, it must be noted that even the notions of identity and real distinction come to be the subject of controversy during the high and later Middle Ages, and this too has the result of complicating the debate

over whether relations are identical to their foundations.[63] For all these reasons, therefore, we must be careful not to identify too closely the debate between reductive and non-reductive realists with the debate over whether relations are identical to their foundations.

5. Non-Paradigmatic Relational Situations

So far we have been focusing only on the medieval discussion of paradigmatic relational situations -- that is, relational situations conforming to the analysis suggested in Aristotle's *Categories*. According to this analysis, as we have seen, when a judgment of the form '*aRb*' is true, what makes it true is nothing but *a* and *b* and a pair of accidents inhering in them, *F* and *G*, which correspond, respectively, to the concepts '*R*' and, its converse, 'R^{-1}'. Although this analysis is suggested by Aristotle's discussion in the *Categories*, it is clear from some of his later works, most notably the *Metaphysics*, that Aristotle does not think all relational situations can be made to conform to it. Thus, in *Metaphysics* V, he suggests that there are some relational situations in which substances are related, not by a pair of accidents, but by a single accident belonging to just one of them. Here he cites the example of intentional relations. Thus, if it is true that Simmias is thinking about Socrates, what makes this true is nothing but Simmias, Socrates, and an accident of Simmias. For the sake of convenience, let us hereafter refer to relational situations that do not conform to the paradigm of the *Categories* as *non-paradigmatic relational situations.*

Although medieval philosophers did not have direct access to Aristotle's *Metaphysics* until the mid-twelfth century, they did feel pressure from other, largely theological sources to admit something like his non-paradigmatic relational situations. On the standard medieval conception of deity, God is an absolutely perfect being, where this is taken to imply that God not does not have any accidents, is immutable, and hence cannot undergo any real change. On this conception of deity, however, it is difficult to explain God's relational features. As Augustine points out in book V of his *De Trinitate*, the difficulty can be expressed in a particularly acute form with respect to the Christian doctrine of creation, according to which God freely created the universe.[64] This doctrine suggests that at one time God lacks, and at a later time acquires, a contingent or accidental relation -- namely, that of being creator. But then does it not also require that in creating the universe God underwent a real change? And what about the claim that there are no accidents in God?

Augustine's solution, which is taken up and developed by medieval philosophers, is to say that when God acquires a new relation, this is not to be explained in terms of any properties or accidents of him, but is rather to be explained in terms of properties or accidents of the things to which he is related. Thus, in the case of creation Augustine says:

> Even though [God's substance] begins to be [truly] spoken of [as related to a creature] at some time, still nothing is to be understood to have happened to the divine substance itself, but only to the creature in relation to whom it is spoken of.[65]

On the basis of theological considerations, therefore, Augustine is led to something like Aristotle's non-paradigmatic relational situations. For according to him what makes it true that God is related to his

creatures is nothing but God, the creatures, and a monadic property or accident of the latter.

Interestingly, Augustine does not think that the case of God is unique, but also suggests that there are non-theological cases in which things are related solely in virtue of the properties or accidents of other things. Thus, a coin, he says can increase or decrease in value solely in virtue of the intentional states of human beings.[66] Boethius, in a treatise also known as *De Trinitate*, discusses these same sorts of issues and in the course of doing so adds yet another non-theological example -- a variation of which comes to be the standard medieval example of a non-paradigmatic relational situation. Consider a man who walks up beside a stationary column. In this sort of case, medieval philosophers like to say, the column comes to be to the right of the man, but solely in virtue of a property of the man.[67]

Thus, even before medieval philosophers had direct access to Aristotle's *Metaphysics* they were led to acknowledge the existence of the type of relational situations mentioned there. Of course, once the relevant texts of Aristotle became available, the medievals worked hard to connect their discussions with these texts. Indeed, when the issue of God's relation to his creatures is taken up in the thirteenth century -- an issue that becomes one of the foci of medieval discussions of relations generally -- medieval philosophers often made direct appeals to Aristotle's discussion in *Metaphysics* V.[68]

5.1 Relations of Reason

So far, then, we have seen that medieval philosophers are committed to recognizing at least one type of non-paradigmatic relational situation -- namely, those involving a pair of substances and a single accident inhering in just one them. As we might expect, medieval philosophers disagree about the precise nature of the accidents involved in these situations. Reductive realists, of course, identify them with ordinary, non-relational accidents, whereas non-reductive realists identify them with accidents of a *sui generis* type. Thus, when Simmias is thinking of Socrates, the reductive realist will appeal to nothing more than a quality of Simmias, whereas the non-reductive realist will also postulate an accident distinct from, but necessitated by Simmias's quality.

For our purposes, however, what is most interesting about the type of relational situation in question is the complication it presents for both reductive and non-reductive realists. In paradigmatic relational situations, as we have seen, there is always a distinct property or accident corresponding to each member of the relevant pair of converse relational concepts. Thus, when Simmias is taller than Socrates, there is one accident corresponding to the concept ‘taller than’ (namely, an accident of Simmias) and one accident corresponding to the concept ‘shorter than’ (namely, an accident of Socrates). But now consider a situation such as Simmias's thinking about Socrates, or God's being related to a creature -- that is, a situation where two substances are related by a property or accident inhering in only one of the *relata*. What is to be said about the relationship between the relevant property and concepts in situations of this sort? Obviously, this is a question that arises regardless of how one analyzes the nature of the accident itself.

Initially, we might expect medievals to respond to this by saying that, in such situations, there is a single

accident corresponding to both members of the relevant pair of relational concepts. Thus, if Simmias is thinking about Socrates, one and the same thing corresponds to both the concepts 'thinking of' and 'thought about', namely, an accident of Simmias. The problem with this suggestion, however, is that it leads to the same sort of difficulties we encountered earlier for identifying relations with pairs of accidents taken jointly. Socrates's being thought about appears to be in Socrates and Socrates alone. But if we identify this relation with an accident of Simmias, then we shall have to say that Socrates's being thought about is not in Socrates after all, but only in Simmias. Although medievals do allow for cases of what they call *extrinsic denomination* -- that is, cases where a property or accident of one thing is predicated of something else -- they typically do not allow for this in the case of relations. That is to say, relations are typically regarded as intrinsic to the subjects of which their corresponding terms or concepts are predicated.[69] Evidently, therefore, the relevant accident of Simmias can correspond to the concept 'thinking of', but not to the concept 'thought about'. But, then, we still need to know what corresponds to this latter concept.

Now perhaps it will be suggested that, in the absence of any property or accident of Socrates to correspond to the concept 'thought about', Socrates himself can serve as the correspondent. In that case, however, we should have to admit that an individual substance is a relation (for according to the standard medieval characterization of relations, whatever corresponds to a relational concept is a relation). But such an admission goes against deep-seated intuitions deriving from the *Categories*. As we have seen, Aristotle not only identifies relations with accidents in the *Categories*, but intentionally characterizes relations in such a way as to exclude substances from this category. But then we still lack a solution to our problem. If there is no property or accident of Socrates to correspond to the concept 'thought about', and neither Socrates nor a property of anything else can correspond to it, then what, if anything, can?

It is at this point that the medieval notion of a relation of reason (*relatio rationis*) becomes important. Medieval philosophers often say that even if there are relational situations involving only a single accident, nonetheless we must still *conceive* of these situations *as if* they involved a pair of accidents, one belonging to each of the related things.[70] Like Boethius, the medievals accept the view that relations cannot be understood to exist by themselves or apart from their correlatives. Relations, they say, always come in pairs. Perhaps this is because they think our understanding of relational situations in general is based on our understanding of the paradigmatic cases, which always do involve pairs of accidents. In any case, medieval philosophers take the fact that relations always come in pairs to show that even if there is no real or extramental property in Socrates that accounts for his being thought about by Simmias, we must nonetheless *conceive* of this situation as if there were one and, as it were, *project* this property onto Socrates. Since such projections depend for their existence on the activity of the mind, medieval philosophers refer to them as beings of reason (*entia rationis*). And their suggestion is that we take these beings of reason to be the items corresponding to or signified by concepts such as 'thought about'.

The notion of a being of reason, or more specifically the notion of a relation of reason, does not appear to have been invoked in the Latin west before the thirteenth century, when Aristotle's *Metaphysics* and certain Muslim philosophical commentaries and treatises derived from it began to circulate widely. The notion of a relation of reason is not to be found explicitly in the works of Aristotle, though in the *Metaphysics* he does distinguish real beings from beings of reason.[71] Relations of reason are, however,

explicitly invoked by certain Muslim philosophers, most notably Avicenna (d. 1037), and it may well be that the distinction between real relations and relations of reason makes its way into the Latin west because of them.

However that may be, once the distinction is introduced in the Latin west, it becomes pervasive -- so pervasive, in fact, that even philosophers, such as Ockham, who complain that such a distinction is "not to be found in the writings of Aristotle" and that "'relation of reason' is not a philosophical term", nevertheless feel compelled to give some account of it in order to preserve common usage.[72] The pervasiveness of this distinction is explained at least partly by the fact that medieval philosophers think it can be used to clarify and explain a number of troublesome non-paradigmatic relational situations. Thus, by the end of thirteenth century, most philosophers explain the doctrine of creation in terms of this distinction, saying that creatures are related to God by a real relation, but God is related to them by a mere relation of reason.[73] Again, they often use the distinction to clarify certain cases of relational change. Thus, when a substance acquires a new relation without undergoing any real change this is often explained by saying that the substance acquired a mere relation of reason.[74] Finally, some medieval philosophers use relations of reason to identify a sense in which God can have accidents after all. Since relations of reason are mere projections (i.e., properties a thing has by virtue of the activity of some mind), it is possible to conceive of them as accidents in a broad sense -- that is, as properties or features that a thing can both acquire and lose. But since the acquisition or loss of these properties does not require a subject to undergo any real change, it is sometimes said that there is no reason in principle why even God should not have accidents of this sort.[75]

5.2 A Shifting Conception of Relations

The distinction between real relations and relations of reason has a number of important consequences for the development of medieval discussions of relations. For one thing, it enables philosophers to develop a number of further refinements and distinctions within the category of relations. By the mid-thirteenth century, for example, it becomes common to say that the category of relations is unique in allowing mere beings of reason among the things signified by its terms. To quote from Aquinas who is representative in this regard:

> The other genera, by virtue of what they are, posit something in extramental reality. Thus, quantity by virtue of the fact that it is quantity posits something. But relation alone is such that, by virtue of what it is, it does not posit anything in extramental reality, for it does not predicate *something* but *toward something*. Hence we find certain relations that do not posit anything in extramental reality, but only in reason.[76]

Again, Aquinas and others appeal to this special feature of the category of relations (namely, that the things signified by its terms can either be real beings or mere beings of reason) to provide a systematic division of relations or pairs of correlatives into three different types, depending on whether the members of these pairs are both real, both conceptual, or mixed (i.e., one member is real, the other conceptual). To quote again from Aquinas:

> It must be known that, since a relation requires two *relata*, there are three ways in which it can be something real or conceptual:
>
> [1] Sometimes it is a mere being of reason on the part of both *relata*, namely, when the order or [relative] disposition cannot exist between things except in virtue of the apprehension of reason alone. For example, when we say that something is identical to itself. For in virtue of the fact that reason apprehends one thing twice, it regards it as two; and in this way it apprehends a certain [relative] disposition of a thing to itself. And the same thing is true of all relations between being and non-being, which reason forms insofar as it apprehends a non-being as a certain *relatum*. Again, the same is true of all relations that follow upon the activity of reason, such as genus and species, and the like.
>
> [2] Now there are other relations that are real as regards both *relata*, namely, whenever there is a [relative] disposition between two things in virtue of something really belonging to each of them -- as is clear from all relations that follow on quantity, such as large and small, double and half, and things of this sort. For there is a quantity in both *relata*. And the same is true of relations that follow on action and passion, such as mover and movable, father and son, and the like.
>
> [3] Sometimes, however, a relation is something real in one of the *relata* and a mere being of reason in the other. And this happens whenever the two *relata* do not belong to a single order. For example, sense perception and knowledge are related to things that are sensible and intelligible. But insofar as the latter are things existing in extramental reality, they are outside the order of sensible and intelligible being. And so there is a real relation in the knowledge and sense perception in virtue of the fact that they are [really] ordered to things that can be known or sensed. However, things [that can be known or sensed] are outside this sort of order [when] considered in themselves, and hence there is not really a relation in them to knowledge or sense perception. On the contrary, there is only a relation in them in accordance with reason, insofar as the intellect apprehends them as terms of the relations of knowledge and sense perception. This is why the Philosopher says in *Metaphysics* V that they are spoken of relatively, not because they are related to other things, but because other things are related to them. Similarly, being to the right is not said of a column unless it is placed to the right of some animal. Hence a relation of this sort is not really in the column but in the animal.[77]

In this passage, Aquinas contrasts the relations involved in paradigmatic relational situations -- namely, relations of the second type -- with the relations involved in two different sorts of non-paradigmatic relational situation. We are already familiar with relations of the third or ‘mixed’ type -- which are comprised by pairs of accidents only one of whose members is real -- from our discussion of creation and intentional relations. Moreover, we can see that Aquinas's discussion of these relations follows the common practice of connecting them with both Aristotle's discussion in the *Metaphysics* and the Boethius-inspired example of the column. We have yet, however, to encounter relations of the first type. These are

relations comprised by pairs of properties or accidents both of whose members are beings of reason. As an example of this type of relation, Aquinas gives self-identity. And his view is that when we conceive of a situation involving this sort of relation -- say Socrates's being identical to himself -- we conceive of it both as if it involved two things ("a relation requires two *relata*" and hence "reason apprehends the one thing twice"), and as if the two things were ordered to each other by a pair of properties (or "[relative] dispositions"). Obviously, however, there are not two distinct things in extramental reality to serve as the *relata* of the relation of self-identity, much less two properties by which such *relata* are related. Like many other medievals, therefore, Aquinas concludes that in this case the relations (or relative dispositions) are not real, but mere beings of reason.[78]

Initially the claim that self-identity is a relation of reason might seem worrisome. For insofar as relations of reason depend for their existence on the activity of the mind, it would seem to follow that something's being self-identical is dependent on the activity of the mind. But that seems absurd. As medieval philosophers recognize, this sort of worry is perfectly generalizable, and so can be raised not only for situations involving pairs of relations of reason, but also for situations involving a single relation of reason. Thus, as Aquinas points out in one of his disputed questions, it might even lead one to doubt whether God's relation to his creatures can be considered a relation of reason:

> For if there were no created intellect in existence, God would still be Lord and Creator. But if there were no created intellect in existence, there would not be any beings of reason. Hence "Creator", "Lord", and terms of this sort, do not express relations of reason.[79]

This sort of worry about relations of reason helps to explain what is perhaps their most significant effect on the medieval discussion of relations -- namely, a gradual shift away from the traditional Aristotelian characterization of relations. On this characterization, as we saw earlier, relations are identified in terms of their metaphysical function -- that is to say, they are characterized as the items that actually serve to relate things. But in order to maintain that things can be self-identical apart from the activity of any mind, while at the same time maintaining that self-identity is a relation of reason, medieval philosophers have little choice but to move away from the traditional characterization. And of course the same thing is true in the case of God's relation to his creatures. Thus, as Aquinas says in reply to abovementioned doubt:

> A man is really (and not merely conceptually) identical to himself, even though his relation [of self-identity] is a being of reason. And the explanation for this is that the cause of his relation is real -- namely, the unity of his substance, which our intellect considers under the aspect of a relation. In the same way, the power to compel subjects is really in God, and our intellect considers this power as ordered to the subjects because of the subjects' order to God. It is for this reason that he is really said to be Lord, even though his relation is a mere being of reason. And for the same reason it is evident that he would be Lord [Creator, etc.] even if there were no created intellect in existence.[80]

In this passage, Aquinas makes it clear that in cases involving relations such as self-identity or God's relation to the world the *relata* are related, not by their relations (since these are mere beings of reason and hence dependent on the activity of the mind), but by what he refers to here as the *cause of* their

relations.[81] Now, in the case of a man's being self-identical, Aquinas says the cause is just “the unity of his substance”, where by this he seems to mean that what makes a man identical to himself is just the man himself. Again, in the case of God's being Lord he says that the cause is “the power to compel subjects”. In the case of God, however, Aquinas does not think the power to compel subjects is distinct from its subject, namely, the divine nature. Hence, he maintains that what makes it true that God is Lord is nothing but God, his creatures, and some property or attribute of the creatures, namely, their dependence for their existence on God.

In effect, therefore, reflection on relations of reason brings about a shift away from the conception of relations as items that relate, and thus forces medieval philosophers to fall back on what they might otherwise have thought of as an equivalent characterization, namely, the view that relations are items corresponding to or signified by our relational concepts. Thus, even if self-identity or God's relation to the world is a mere being of reason, and hence does not actually relate its subject to anything, nonetheless it can still be regarded as a relation on the grounds that it is signified by a relational concept. Now obviously this shift away from the traditional Aristotelian conception has the awkward consequence that things can be related even if their relations do not exist. Thus, Socrates can be identical to himself even if there is no self-identity, God can be Lord of creation even if his relation of Lordship does not exist, and more generally, a judgment of the form ‘*aRb*’ can be true, even when no judgment of form ‘*R*-ness exists’ is true. Of course, there is nothing ultimately incoherent about this consequence, provided we keep in mind that the relations in such cases are mere beings of reason. Nonetheless, accepting this consequence does force medieval philosophers to deny what at least initially appears to be a truth of reason, and at any rate is part of common sense -- namely, that things are related by their relations.[82]

Some philosophers, such as Aquinas, assume that the departure from the traditional Aristotelian characterization of relations is required only in non-paradigmatic relational situations. By the end of the Middle Ages, however, this sort of departure is so common and familiar that philosophers no longer feel the need to regard it as exceptional. Thus, Ockham eventually adopts a view according to which all relations depend for their existence on the activity of the mind. Indeed, things are so changed by the time of Ockham that he feels free not only to reject the traditional Aristotelian characterization of relations, but also to modify the standard medieval alternative to it. Thus, on his preferred characterization, relations are the items corresponding, not to all of our relational concepts, but to just one of them -- namely, the concept ‘relation’. As Ockham sees it, moreover, the concept ‘relation’ is a term of second intention -- that is to say, a term to which only concepts correspond. Thus, even though Ockham insists that many judgments of the form ‘*aRb*’ are true independently of the mind, he nonetheless maintains that properly speaking relations exist only in the mind as concepts.[83] This helps to explain why he often expresses his view using formulas such as: “This white thing really is similar, even though similarity is not really in this white thing.”[84]

5.3 Relations as Substances

Although relations of reason force a shift away from the Aristotelian characterization of relations, it is important to recall that they were originally invoked to preserve the deep-seated Aristotelian conviction

that no substance is a relation. Thus, as we saw, in order to avoid saying that Socrates is signified by the concept ‘thought about’, when he is being thought about by Simmias, medieval philosophers invoke the notion of a relation of reason: it is not Socrates, but a relation of reason, they say, that corresponds to the concept in question, and in this way avoid the consequence that a substance such as Socrates is a relation. And of course the same sort of invocation is needed to avoid saying that Socrates corresponds to the concept of ‘self-identical’ or that God corresponds to the concepts ‘Lord’ or ‘Creator’. Given the lengths to which medieval philosophers are willing to go, in situations such as these, to preserve the thesis that no substance is a relation, it is all the more interesting that there is at least one case -- namely, the Christian doctrine of the Trinity -- in which they are forced to admit that even this Aristotelian thesis cannot be upheld.

According to the Christian doctrine of the Trinity, God exists in three persons: Father, Son, and Holy Spirit. As this doctrine was typically understood during the Middle Ages, it implies not only that God possesses certain relations -- such as fatherhood and sonship -- but also that he possess them independently of the activity of any mind. As Aquinas says in his *Summa Theologiae*:

> Someone is said to be a father only by virtue of his fatherhood, and someone is said to be a son only by virtue of his sonship. Therefore, if [the relations of] fatherhood and sonship are not really in God, it follows that God is not a Father or Son really, but merely according to a concept of the mind -- which is the Sabellian heresy.[85]

Now when the claim that there are real relations in God is combined with another doctrine that was ubiquitous in the Middle Ages, namely the doctrine of divine simplicity, the conclusion that God (and hence at least one substance) is a relation seems to follow necessarily. For as the doctrine of divine simplicity is typically understood, there is no real distinction to be drawn between God and any of his attributes. Thus, if God is good, he is identical to his goodness; if he is wise, he is identical to his wisdom. By parity of reasoning, therefore, if God is a father or son, he must be identical to his fatherhood and sonship. Again, Aquinas is perfectly representative in this regard: “Whatever is in God *is* his nature . . . It is thus clear that a relation really existing in God is identical to his nature according to reality, and does not differ from it except according to a concept of the mind.”[86]

The doctrine of the Trinity, therefore, brings us to what is perhaps the medievals' greatest departure from Aristotle. Some medievals, however, see the Trinity not as providing a counterexample to Aristotle's thesis that no substance is a relation, but rather as calling our attention to a restriction on its range of applicability. Aquinas, for example, appears to think that the thesis was specifically formulated to apply only to the case of creatures,[87] and to some extent this is plausible, since obviously Aristotle was not thinking about theological examples such as the Trinity when he formulated it. Interestingly, however, other philosophers think that the thesis does not hold even in the case of all creatures. Thus, Gilbert of Poitiers (d. 1154), in a discussion of Boethius's *De hebdomadibus*, suggests that creaturely goodness is a relation, indeed, just the relation of being created by God. As I read him, moreover, Gilbert takes this relation to be nothing over and above the creature itself, so that in the case of creatures it is individual substances that correspond to the concept ‘created by’ and hence qualify as relations. Like Aquinas, however, Gilbert appears to think of these sorts of cases, not as providing counterexamples to Aristotle's

thesis, but rather as telling us something about the scope of its applicability. According to Gilbert, there is a distinction to be drawn between *natural philosophy*, which he says deals with natural things, and other areas of intellectual inquiry, including *theology* and *ethics*, which he says deal with a broader scope of things.[88] And Gilbert's suggestion is that if we restrict our attention to natural philosophy, as no doubt Aristotle did, then like him we will be led to the conclusion that no substance is a relation.[89]

Although Gilbert and Aquinas work hard to preserve, at least in non-theological contexts, something like the Aristotelian thesis that no substance is a relation, not all medieval philosophers feel the need to do so. Indeed, as Middle Ages progress, there appears to be a gradual shift, even in non-theological contexts, towards allowing substances to be relations, or at least towards allowing them to be the primary *significata* of our relational concepts. Here again Ockham appears to be an important transitional figure. Thus, he breaks with tradition in allowing that even self-identity is a real relation, or at least that it is “real . . . in the same way that similarity and equality are”.[90] Indeed, on Ockham's view, which becomes influential in the generations following him, it turns out that substances are signified by most of our relational concepts. For apart from some species of quality, Ockham thinks there is no real distinction to be drawn between substances and any of there accidents. According to him, therefore, relational situations do not typically involve anything more than individual substances.[91]

6. A Shift in Paradigms

We are now in a position to appreciate, I think, the main types of views that medievals developed concerning the nature and ontological status of relations, as well as the main historical and dialectical considerations that helped to shape them. As we have seen, with the exception of thinkers such as Peter Aureoli, medievals appear to have been drawn (almost to a person) to a form of realism about relations, one according to which at least some judgments of the form ‘*aRb*’ are true independently of the mind. There is some disagreement as to the precise analysis of the situations that makes these sorts of judgments true, but even here the medievals work out their views from within a common framework provided by Aristotle's *Categories*. Thus, it is generally agreed that relational situations do not include anything corresponding to the notion of a polyadic property, but instead include only substances and their monadic properties or accidents. The main disagreements, therefore, are best characterized as disagreements about the extent to which the proper analysis ought to conform to the paradigm suggested by the *Categories*. Prior to the fourteenth century, as we have seen, medievals tended to follow Aristotle in claiming that things are related by their accidents, and hence that relational situations typically involve not only pairs of substances, but pairs of monadic properties or accidents as well. As a result, one of the most pressing questions during this period concerns the precise nature of the accidents involved in relational situations. Reductive realists, as we have seen, identify them with ordinary, non-relational accidents such as quantities or qualities, whereas non-reductive realists identify them with monadic properties of a *sui generis* type.

With the advent of the fourteenth century, however, important changes begin to take place in the medieval discussion of relations. Philosophers and theologians continue, of course, to allow for situations in which substances are related by their accidents, and hence to worry about the precise nature of the accidents

involved in these situations. But at this point there is a decided shift toward regarding such situations as exceptional. As we have seen, there was always strong theological pressure to allow for at least some departures from the Aristotelian paradigm. But what appears to have happened over time is that these departures come to seem less and less peculiar to medievals, and eventually the departures themselves provide the basis for a new analysis of relational situations -- one according to which substances are the items responsible for relating. Around this same time, moreover, Ockham and his followers, most notably John Buridan, institute another sort of change, namely, a shift away from a standard medieval semantic characterization of relations. Prior to the fourteenth century, philosophers and theologians typically assume that the term "relation" signifies whatever it is in a relational situation that does the relating -- though here again theological considerations force them to allow for certain exceptions. By the time of Ockham, however, we get a complete break with this standard characterization. Thus, whereas earlier philosophers and theologians would allow the term "relation" to signify a being of reason in certain cases, such as creation, Ockham and his followers maintain that "relation" is a term of second intention, and so strictly speaking always signifies beings of reason. With Ockham, therefore, we have not only a complete severing of the connection between relations and those items in relational situations that actually do the relating, but also the advent of a new -- and, I might add, fairly harmless -- form of anti-realism.[92]

In the end, therefore, I think it is fair to say that the fourteenth century marks a shifting of medieval paradigms both with respect to the proper analysis of relational situations and with respect to the proper characterization of relations. I hasten to add, however, that these shifts cannot be fully explained in terms of developments within the medieval discussion of relations, but are instead part-and-parcel of broader theoretical shifts in medieval accounts of the relationship between mind, language, and reality -- shifts which are closely associated with the rise of late-medieval nominalism generally.[93]

Bibliography

[Note: This bibliography contains only items referred to in the notes and a few other selected items of interest. Further discussion of medieval theories of relations, as well as further bibliographical references, can be found in Henninger 1989, Olson 1987, and Weinberg 1965. For a contemporary defense of the view I have been calling "realism without polyadic properties", see Campbell 1990 and Fisk 1973.]

Notes to Medieval Theories of Relations

Notes

1. For the record, the other categories are action, passion, time, place, position, and habit.

2. In medieval philosophy, "similar to" (or "*similis*" followed by the dative case) just means *same in quality as*.

3. In *Categories* 7, Aristotle makes it clear that he thinks the relating properties must be accidents, for according to him no substance is a relation. See *Categories* 7, 8a14f.

4. *Metaphysics* V, 15, 1021a30. All translations of Aristotle are taken, with slight modification, from *The Complete Works of Aristotle*.

5. Augustine discusses both types of theological consideration in *De Trinitate* V, especially pp. 208-215. This text exercises enormous influence on the subsequent medieval treatment of relational situations.

6. Boethius sets the precedent here. In his commentary on the *Categories*, which introduced medieval philosophers to all three terms, he not only alternates among them but explicitly denies that there is any difference in meaning between two of them, namely, "toward something" and "relative": "Whether we say *toward something* or *relatives* makes no difference." Boethius, *In Categorias Aristotelis*, p. 217.

7. *Liber de praedicamentis*, p. 225b.

8. *Categories* 7, 6a36-6b.

9. Medievals rely on context (rather than quotation marks) to distinguish use and mention, and hence employ the same terms to refer both to relations and to the predicates by means of which they are introduced.

10. *Categories* 7, 8a29-35.

11. ST I, q. 13, a. 7, ad 1.

12. *Categories* 7, 8b22-24.

13. *In Categorias Aristotelis*, p. 238.

14. Cf. Weinberg 1965, esp. pp. 61-63.

15. Cf. Albert the Great, *Liber de praedicamentis*, p. 241a-241b; Aquinas ST I, q. 28, a. 4, obj. 5; and the texts of Harclay cited below.

16. See *Physics* III, 202b11-15.

17. *Scriptum super Primum Sententiarum*, fols. 318^{v}a-b. See Henninger 1989, pp. 153-4, n. 12, for the Latin text.

18. *Scriptum super Primum Sententiarum*, fols. 318^{v}a-b.

19. Cf. *Categories* 1, 1a20-1b6.

20. Though following Boethius, medievals argue vigorously for this claim in the context of their discussions of universals. For Boethius's defense of this claim and consequent rejection of realism about substance universals, see Spade 1994, pp. 21-22. For a reconstruction of Boethius's argument and discussion of its historical significance, see Klima 2000 and the texts cited in his notes.

21. 1SN, d. 27, q. 1, a. 1, ad 2.

22. Cf. *Tractatus de quantitate* q. 3 (in *Opera Theologica* x, p. 104). There is some debate about how exactly Ockham's ‘razor-type’ claims are to be interpreted. For relevant discussion, see Boler 1985 and the notes cited in his article; cf. also Spade 1999, pp. 100-117.

23. *Liber de praedicamentis*, 222b. For further discussion, see Brower 2001.

24. *Scriptum super Primum Sententiarum*, fols. 318^{v}a-b. For useful discussion of Aureoli's views, see Henninger 1989, pp. 150-173.

25. In the early modern period, philosophers habitually speak of relations as the “products of comparison” or “results of thought”, while at the same time allowing for things to be related apart from the activity of any mind. See, e.g., Locke, *An Essay Concerning Human Understanding*, bk. 2, chap. 2; Hume, *A Treatise of Human Nature*, bk. 1, pt. 1, sec. 5; and Leibniz, *Philosophische Schriften*, vol. 2, p. 486. Cf. also Henninger 1989, pp. 184-186; Olson 1987, pp.37-43; and Cover and O'Leary-Hawthorne 1999, pp. 58-86.

26. See *Liber de praedicamentis*, 222b-223a.

27. Cf. ST I, q. 28, a. 2, corpus; cf. also Veckley 1965, pp. 28-9.

28. In his commentary on Aristotle's *Metaphysics*, Avicenna suggests that most of his contemporaries endorse a form of anti-realism. For a translation and discussion of the relevant texts, see Marmura 1975. On the Mutakallim•n, cf. Weinberg 1965, 89-91.

29. Part of Aureoli's innovation consists in the way he tries to accommodate this intuition. See Henninger, 1989, pp. 166-68.

30. *Ordinatio* I, d. 30, q. 1 (in *Opera Theologica* iv, pp. 316-317). Cf. also Scotus, *Ordinatio* II , d. 1, q. 5, n. 224 (in *Opera Omnia*); Aquinas, *De potentia*, q. 7, a. 9.

31. *De potentia*, q. 7, a. 9.

32. Cf., e.g., Aquinas, ST I, q. 28, a. 1 and *De potentia* q. 8, a.1.

33. This summary provides what I take to be the point of Albert's difficult discussion in *Liber de praedicamentis*, 224a-224b. For a detailed defense of this interpretation, and its contemporary relevance, see Brower 2001.

34. *Summa Logica* I, c. 51 (in *Opera Philosophica* i, p. 171); cf. Loux, 1974, p. 171.

35. *In Categorias Aristotelis*, p. 217.

36. See, e.g., Abelard, *Logica 'ingredientibus'*, pp. 80-95; and Albert the Great, *Liber de praedicamentis*, p. 22.

37. For discussion of Harclay's two views, and their relationship to Scotus's and Ockham's, see Henninger 1989, pp. 98-118.,

38. For a good example of this approach, see Abelard's discussion of universals in his *Logica 'ingredientibus'*, pp. 7-32. For an English translation of this discussion, see Spade 1994, pp. 26-56.

39. *Ordinatio* I, d. 30, q. 2 (in *Opera Theologica* iv, p. 322). Cf. also n. 20 above.

40. Abelard justifies this interpretation on the basis of an analogy to good-making characteristics: just as certain attributes (say, being red, juicy, and sweet) make certain things good, so too, he suggests, certain attributes (such as being-six-feet-tall and five-feet-ten) make certain things to be relative (or related). See

Logica 'ingredientibus', pp. 216-17. For further discussion, see Brower 1998.

41. *Summa logicae* I, c. 49 (in *Opera Philosophica* i, p. 154). Cf. Henninger 1989, p. 120.

42. During the thirteenth and fourteenth centuries, this intuitive view of relational change was often discussed in a connection with an authoritative passage from the *Physics*, where Aristotle says "There is no motion in respect of relation: for it may happen that when one correlative changes, the other can truly be said not to change at all, so that in these cases the motion is accidental". Cf. *Physics* V, 2, 225b11-13.

43. Ockham, *Ordinatio* I, d. 30, q. 3 (in *Opera Theologica* iv, p. 347); cf. also the other texts cited in Henninger 1989, p. 129, n. 31.

44. In passing, however, it should be mentioned that reductive realists also appealed to various forms of an infinite regress argument to support their position. This sort of argument is now typically associated with the absolute idealist, F. H. Bradley, but it was known to philosophers during the Middle Ages and taken by many (including, Ockham and the later Harclay) to show that relations cannot be really distinct from their foundations. Cf. Henninger 1989, pp. 110-112, 121-122 and Adams 1987, vol. 1, pp. 215-250. Again, reductive realists also relied on various forms of what is sometimes called the separation argument. After certain events in the late thirteenth century, including the condemnations of 1277, it was generally agreed that a real distinction between two or more items implies that either can exist in separation from the other—at least by God's power. As the reductive realists were quick to point out, however, this tells against non-reductive realism. For if relations are really distinct from their foundations, then it follows that God can create the foundations without the corresponding relations—and hence (absurdly) that, say, two white things could exist without being similar, or two quantified things without being either equal or unequal. Cf. Harclay, "Utrum Dei ad creaturam sit relatio realis" (hereafter abbreviated "Utrum Dei"), n. 18f. For further references and discussion, cf. also Menn 1997. For a variation of the separation argument, sometimes used against reductive realism, see Klima's discussion of Psuedo-Campsall vs. Ockham in Spade 1999, esp. pp. 123-127.

45. Ockham, however, leans toward this sort of view in several of his *Quodlibetal* questions, where he entertains the idea that abstract relative terms, such as 'similitude', function as collective names, and hence like other such terms ('people', 'army', 'crowd', 'company') refer to several things taken jointly (*conjunctim*). Cf. *Quodl.* VI, q. 8 (in *Opera Theologica* ix, pp. 616-617) and q. 25 (pp. 681-682).

46. "Utrum Dei", n. 46. All translations of Harclay are adopted, with slight modification, from MacDonald (forthcoming).

47. "Utrum Dei", n. 47.

48. Harclay's discussion is complicated and my interpretation is by no means uncontroversial. For an alternative interpretation of this discussion, see Henninger 1989, pp. 112-117.

49. Again, the idea here is that, by itself, Simmias's height is merely *potentially* relative-making, and it only becomes *actually* relative-making in the presence of another height, including Socrates's.

50. Cf. Armstrong's description of his own view in Crane 1996, esp. pp. 39-41.

51. For a formal reconstruction of this sort of view, see Klima 1991.

52. “Utrum Dei,” n. 43.

53. *Quodl*. VI, q. 25 (in *Opera Theologica* ix, p. 679).

54. M*etaphysica*, p. 266a.

55. Harclay uses the term “toward-ness” (*aditas*) in his question on relations (see “Utrum Dei,” n. 50), whereas Aquinas often uses “disposition” (*habitudo*) or “relative disposition” (*relativa habitudo*), and eventually comes to prefer “order” (*ordinatio*). For a helpful discussion of some of the terms used by medieval philosophers to signify relations, see Schmidt 1986, esp. pp. 133-40.

56. Especially worth mentioning in this context is Addis 1989 (see esp. pp. 27-46). Addis identifies several other contemporary or near-contemporary philosophers who hold this sort of view (including Meinong, Husserl, Bergmann, and Searle), but anyone holding a form of the so-called adverbial theory of consciousness would also appear to be a candidate.

57. Harclay explicitly addresses this sort of non-reductivist line in “Utrum Dei,” n. 10f.

58. Cf. *Metaphysica*, 266b-267a, ad 1.

59. *Metaphysica*, 267a, ad. 3.

60. *In V Phys*., lect. 3, n. 8.

61. *In V Phys*., lect. 3, n. 8.

62. For this interpretation of Aquinas, see Henninger 1989, pp. 13-28.

63. Thus, according to Henninger, the proper description of Aquinas's view about relations and their foundations will vary depending on which criteria one uses for identity and real distinction. See Henninger 1989, 29-31.

64. Augustine, *De Trinitate*, pp. 224-27.

65. *De Trinitate*, p. 226. ("…quamvis temporaliter incipiat dici, non tamen ipsi substantiae dei accidisse intelligatur sed illi creaturae ad quam dicitur")

66. *De Trinitate*, p. 226. Augustine introduces the example of the coin in the course of defending his views about of creation. Thus, he says, if a coin can change its relations solely in virtue of changes in the properties of something else, "how much easier ought we to accept this of the unchangeable substance of God?" (ibid).

67. Boethius's example actually involves a man walking up beside another, stationary human being. See *De Trinitate* 5. Medieval philosophers, however, prefer to use the example of a man and an immobile column, and over time come to speak as if this were Boethius's own example. Thus, as Harclay says at one point: "Boethius offers the example of a column's being to the right at the end of *De Trinitate*." See "Utrum Dei," n. 72.

68. Peter Lombard (c. 1095-1160) discusses the relationship between God and creatures in the first book of his *Sentences*, an influential summary of Christian doctrine. From the mid-thirteenth through the mid-fourteenth century, every student who earned a baccalaureate in theology was required to lecture and comment on Peter's text. As a result, commentaries on the first book of this text (around distinction 30) become the *locus classicus* for medieval discussions of relations. Cf. Henninger 1989, p. 8.

69. This way of thinking about relations derives from a late 12th-century work of unknown authorship (but traditionally ascribed to Gilbert of Poitiers) called *Liber sex principiorum*. This work distinguishes the first four Aristotelian categories (substance, quantity, quality, and relation) as intrinsic and the last six categories as extrinsic. For a representative treatment of the categories which follows this division, see Aquinas's discussion in *In V Met*., lect. 9, n. 892; cf. also the commentary in Wippel 1987. Even Aquinas, however, sometimes allows for extrinsic denomination in the case of relations. Cf. 1SN d. 40, q. 1, a. 1.

70. Cf., e.g., Aquinas, *De potentia* q. 1, a. 1, ad 10.

71. Cf. *Metaphysics* IV, 1 (esp. 1003a32-b11) and V, 7 (esp. 1017a31-35).

72. *Ordinatio* I, d. 30, q. 5 (in *Opera Theologica* iv, pp. 385-86). For a discussion of Ockham's distinction between real relations and relations of reason, see Henninger 1989, 136-40.

73. Cf. Henninger 1989.

74. In one of his early works, *Super Dionysium De divinis nominibus*, Albert the Great identifies all

relations acquired as a result of mere Cambridge changes as relations of reason—apparently overlooking the possibility of acquiring *real* relations in the same way (as in the case of Socrates's becoming shorter than Simmias as result of Simmias's growth). For the relevant texts of Albert, and helpful discussion, see MacDonald 1991, pp. 31-55 (esp. 42-47). No other medieval philosopher I know of makes this sort of identification, and Albert himself comes to reject it in some of his later works. Thus, as I indicated in section 4b above, in his *Metaphysica* Albert explicitly allows for cases in which a substance can acquire real relations without undergoing any real change, and uses the distinction between relations and relational accidents to explain how this is possible.

75. In *Monologium* c. 25, Anselm distinguishes those accidents which require a change in their subject from those that do not, and suggests that even God may have accidents of the latter sort (though as he goes on to explain, 'accidents' of this latter sort are accidents only according to an improper way of speaking). In "Utrum Dei," Harclay develops this distinction between two types of accident at greater length, and attempts to connect it not only with Anselm but also with Augustine and Boethius (cf. esp. nn. 110-120).

76. *De veritate*, q. 1, a. 5, ad 15.

77. ST I, q. 13, a. 7, corpus.

78. Interestingly, this same line of reasoning leads some philosophers to deny that self-identity is a relation at all. Consider, for example, the following passage from Harclay's "Utrum Dei," n. 32: "real identity is not a real relation, because it lacks one condition that is necessary for being a relation (and which it is impossible for something that is identical and that to which it is identical to satisfy), namely, real distinctness of *relata*. This condition is satisfied in the case of distinct things but not in the case of something that is one and the same [as itself]. For that reason, distinctness is a relation but identity is not."

79. *De potentia*, q. 7, a. 11, obj. 4.

80. *De Potentia* q. 7, a. 11, ad 3-5.

81. What Aquinas here refers to as 'cause' he elsewhere refers to as the 'foundation in reality (*fundamentum in re*)' of a being of reason (cf., e.g., SN1 d. 19, q. 5, a. 1). In the case at hand, therefore, the relevant causes are just the extramental foundations of the relations.

82. Medieval philosophers often apply this consequence to cases involving privations, such as blindness. For privations involve negation, which is typically regarded as a being of reason. Thus, it is commonly said that Homer would lack sight, even if Homer's blindness did not exist. For the truth of the latter claim depends for its existence on the activity of the mind. For further discussion and references, see Klima 1993.

83. Ockham does, however, want to maintain (with Aristotle) that relation is a real category or *genus generalissimum*. He does this by identifying a loose sense in which relations can be said to exist outside the mind, and indeed interprets Aristotle's own way of speaking along these lines: “according to the Philosopher's view, ‘relation’ is a category of the real not in the sense that it signifies things outside [the mind] … but rather in the sense that its species [i.e., specific relational concepts] signify such things [outside the mind].” See *Quodl.* VI, q. 22 (in *Opera Theologica* ix, p. 669); cf. Freddoso and Kelly 1991, p. 564 and Henninger 1989, p. 133.

84. *Quodl.* VI, q. 22 (in *Opera Theologica* ix, p. 669).

85. ST I, q. 28, a. 1, sed contra. Although this passage occurs in the *sed contra*, it is clear from other works that it represents Aquinas's own views. Cf. *De potentia*, q. 8, a. 1.

86. ST I, q. 28, a. 2, corpus.

87. Cf. ST I, q. 28, a. 2, corpus.

88. *The Commentaries on Boethius by Gilbert of Poitiers*, p. 79. Gilbert's division of the intellectual disciplines follows Boethius's discussion in *De Trinitate* 2.

89. Cf. *The Commentaries on Boethius by Gilbert of Poitiers*, pp. 193, 223, and 227. For an excellent discussion of the relevant texts, to which my own discussion is indebted, see MacDonald 1999.

90. *Quodl*. V, q. 27 (in *Opera Theologica* ix, p. 685).

91. One of Ockham's most influential followers, John Buridan (d. 1358/61) even goes so far as to say that everything is a relation (*relativum*, though not *relatio*, which like Ockham he construes as a second intention). For everything can be conceived of in terms of a relative concept, since everything is identical with itself and distinct from everything else. Cf. *Summulae de Dialectica*, 3.4.1.

92. I say “harmless” because, like other medieval realists, Ockham and his followers think many judgments of the form ‘*aRb*’ are true independently of the mind. Nonetheless, because they deny that the term “relation” refers to anything in extramental reality, and hence that strictly speaking relations are concepts or beings of reason, there is a sense in which their view qualifies as anti-realist.

93. For an excellent account of these broader historical developments, see Ashworth 1974; cf. also Klima 2000, and the exchange between Jack Zupko and Gyula Klima (in Klima 1998).

The Medieval Problem of Universals

“The problem of universals” in general is a historically variable bundle of several closely related, yet in different conceptual frameworks rather differently articulated metaphysical, logical, and epistemological questions, ultimately all connected to the issue of how universal cognition of singular things is possible. How do we know, for example, that the Pythagorean theorem holds *universally*, for *all* possible right triangles? Indeed, how can we have any awareness of a potential infinity of all possible right triangles, given that we could only see a finite number of actual ones? How can we universally indicate all possible right triangles with the phrase ‘right triangle’? Is there something common to them all signified by this phrase? If so, what is it, and how is it related to the particular right triangles? The *medieval* problem of universals is a logical, and historical, continuation of the *ancient* problem generated by Plato's (428-348 B.C.) theory answering such a bundle of questions, namely, his theory of Ideas or Forms.

1. Introduction

The inherent problems with Plato's original theory were recognized already by Plato himself. In his

Parmenides Plato famously raised a number of difficulties, for which he apparently did not provide satisfactory answers. Aristotle (384-322 B.C.), with all due reverence to his teacher, consistently rejected Plato's theory, and heavily criticized it throughout his own work. (Hence the famous saying, *amicus Plato sed magis amica veritas*).[1] Nevertheless, despite this explicit doctrinal conflict, Neo-Platonic philosophers, pagans (such as Plotinus ca. 204-270, and Porphyry, ca. 234-305) and Christians (such as Augustine, 354-430, and Boethius, ca. 480-524) alike, observed a basic concordance between Plato's and Aristotle's approach, crediting Aristotle with an explanation of how the human mind acquires its universal concepts of particular things from experience, and Plato with providing an explanation of how the universal features of particular things are established by being modeled after their universal archetypes.[2] In any case, it was this general attitude toward the problem in late antiquity that set the stage for the ever more sophisticated medieval discussions.[3] In these discussions, the concepts of the human mind, therefore, were regarded as posterior to the particular things represented by these concepts, and hence they were referred to as *universalia post rem* ('universals after the thing'). The universal features of singular things, inherent in these things themselves, were referred to as *universalia in re* ('universals in the thing'), answering the universal exemplars in the divine mind, the *universalia ante rem* ('universals before the thing').[4] All these, universal concepts, universal features of singular things, and their exemplars, are expressed and signified by means of some obviously universal signs, the universal (or common) terms of human languages. For example, the term 'man', in English is a universal term, because it is truly predicable of all men in one and the same sense, as opposed to the singular term 'Socrates', which in the same sense, i.e., when not used equivocally, is only predicable of one man.

Depending on which of these items (universal features of singular things, their universal concepts, or their universal names) they regarded as the primary, really existing universals, it is customary to classify medieval authors as being *realists*, *conceptualists*, or *nominalists*. The *realists* are supposed to be those who assert the existence of real universals *in* and/or *before* particular things, the *conceptualists* those who allow universals only, or primarily, as concepts of the mind, whereas *nominalists* would be those who would acknowledge only, or primarily, universal words. But this rather crude classification does not adequately reflect the genuine, much more subtle differences of opinion between medieval thinkers. (No wonder one often finds in the secondary literature distinctions between, "moderate" and "extreme" versions of these crudely defined positions.) In the first place, nearly *all* medieval thinkers agreed on the existence of universals *before* things in the form of divine ideas existing in the divine mind,[5] but all of them denied their existence in the form of mind-independent eternal entities originally posited by Plato. Furthermore, medieval thinkers also agreed that particular things have certain features which the human mind is able to comprehend in a universal fashion, and signify by means of universal terms. As we shall see, their disagreements rather concerned the types of the relationships that hold between the particular things, their individual, yet universally comprehensible features, the universal concepts of the mind, and the universal terms of our languages, as well as the ontological status of, and distinctions between, the individualized features of the things and the universal concepts of the mind. Nevertheless, the distinction between "realism" and "nominalism", especially, when it is used to refer to the distinction between the radically different ways of doing philosophy and theology in late-medieval times, is quite justifiable, provided we clarify what *really* separated these ways, as I hope to do in the later sections of this article.

In this brief summary account I will survey the problem both from a systematic and from a historical point of view. In the next section I will first motivate the problem by showing how naturally the questions

concerning universals emerge if we consider how we come to know a universal claim, i.e., one that concerns a potentially infinite number of particulars of a given kind, in a simple geometrical demonstration. I will also briefly indicate why a naïve Platonic answer to these questions in terms of the theory of perfect Forms, however plausible it may seem at first, is inadequate. In the third section I will briefly discuss how the specific medieval questions concerning universals emerged, especially in the context of answering Porphyry's famous questions in his introduction to Aristotle's *Categories*, which will naturally lead us to a discussion of Boethius' Aristotelian answers to these questions in his second commentary on Porphyry in the fourth section. However, Boethius' Aristotelian answers anticipated only one side of the medieval discussions: the mundane, philosophical theory of universals, in terms of Aristotelian abstractionism. But the other important, Neo-Platonic, theological side of the issue provided by Boethius, and, most importantly, by St. Augustine, was for medieval thinkers the theory of ontologically primary universals as the creative archetypes of the divine mind, the Divine Ideas. Therefore, the fifth section is going to deal with the main ontological and epistemological problems generated by this theory, namely, the apparent conflict between divine simplicity and the multiplicity of divine ideas, on the one hand, and the tension between the Augustinian theory of divine illumination and Aristotelian abstractionism, on the other. Some details of the early medieval Boethian-Aristotelian approach to the problem and its combination with the Neo-Platonic Augustinian tradition *before* the influx of the newly recovered logical, metaphysical, and physical writings of Aristotle and their Arabic commentaries in the second half of the 12th century will be taken up in the sixth section, in connection with Abelard's (1079-1142) discussion of Porphyry's questions. The seventh section will discuss some details of the characteristic metaphysical approach to the problem in the 13th century, especially as it was shaped by the influence of Avicenna's (980-1037) doctrine of common nature. The eighth section outlines the most general features of the logical conceptual framework that served as the common background for the metaphysical disagreements among the authors of this period. I will argue that it is precisely this common logical-semantical framework that allows the grouping together of authors who endorse sometimes radically different metaphysics and epistemologies (not only in this period, but also much later, well into the early modern period) as belonging to what in later medieval philosophy came to be known as the “realist” *via antiqua*, the “old way” of doing philosophy and theology. By contrast, it was precisely the radically different logical-semantical approach initiated by William Ockham (ca. 1280-1350), and articulated and systematized most powerfully by Jean Buridan (ca. 1300-1358), that distinguished the “nominalist” *via moderna*, the “modern way” of doing philosophy and theology from the second half of the 14th century. The general, distinctive characteristics of this “modern way” will be the discussed in the ninth section. Finally, the concluding tenth section will briefly indicate how the separation of the two *viae*, in addition to a number of extrinsic social factors, contributed to the disintegration of scholastic discourse, and thereby to the disappearance of the characteristically medieval problem of universals, as well as to the re-mergence of recognizably the same problem in different guises in early modern philosophy.

2. The Emergence of the Problem

It is easy to see how the problem of universals emerges, if we consider a geometrical demonstration, for example, the demonstration of Thales' theorem. According to the theorem, any triangle inscribed in a semicircle is a right triangle, as is shown in the following diagram:

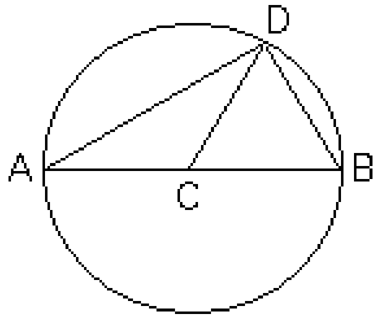

Figure 1. Thales' theorem

Looking at this diagram, we can see that all we need to prove is that the angle at vertex D of triangle ABD is a right angle. The proof is easy once we realize that since lines AC, DC, and BC are the radii of a circle, the triangles ACD and DCB are isosceles triangles, whence their base angles are equal. For then, if we denote the angles of ABD by their vertices, this fact entails that D=A + B; and so, since A + B + D=180º, it follows that 2A + 2B=180º; therefore, A + B=90º, that is, D=90º, **q. e. d.**

Of course, from our point of view, the important thing about this demonstration is not so much the *truth* of its conclusion as *the way* it proves this conclusion. For the conclusion is a universal theorem, which has to concern all possible triangles inscribed in any possible semicircle whatsoever, not just the one inscribed in the semicircle in the figure above. Yet, apparently, in the demonstration above we were talking only about that triangle. So, how can we claim that whatever we managed to prove concerning that particular triangle will hold for all possible triangles?

If we take a closer look at the diagram, we can easily see the appeal of the Platonic answer to this question. For upon a closer look it is clear that, despite appearances to the contrary, this demonstration *cannot* be about the triangle in this diagram. Indeed, in the demonstration we assumed that the lines AC, DC, and BC were all perfectly equal, straight lines. However, if we zoom in on the figure, we can clearly see that these lines are far from being equal; in fact, they are not even straight lines:

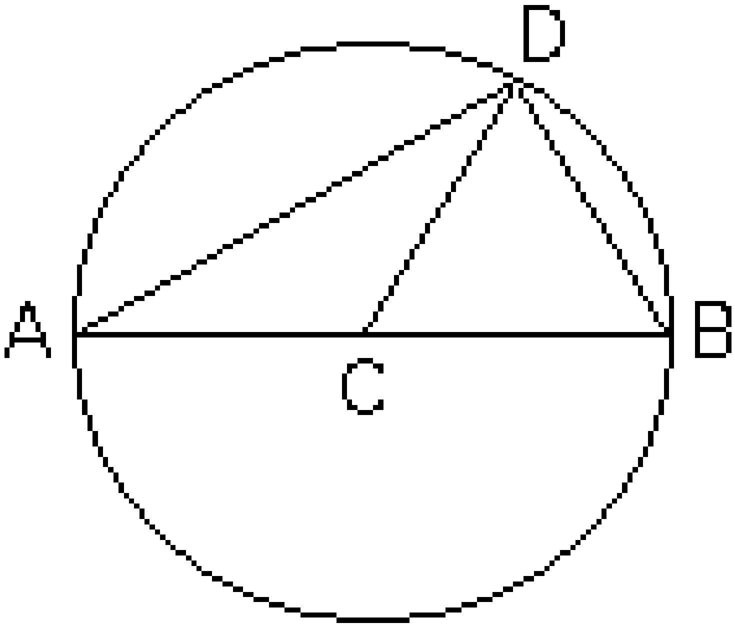

Figure 2. The result of zooming in on Figure 1.

The demonstration was certainly not about the collection of jagged black surfaces that we can see here. Rather, the demonstration concerned something we did not see with our bodily eyes, but what we had in mind all along, understanding it to be a triangle, with perfectly straight edges, touching a perfect circle in three unextended points, which are all perfectly equidistant from the center of the circle. The figure we could see was only a convenient "reminder" of what we are supposed to have in mind when we want to prove that a certain property, namely, that it is a right triangle, has to belong to the object in our mind in virtue of what it is, namely, a triangle inscribed in a semicircle. Obviously, the conclusion applies perfectly only to the perfect triangle we had in mind, whereas it holds for the visible figure only insofar as, and to the extent that, this figure resembles the object we had in mind. But this figure fails to have this property precisely insofar as, and to the extent that, it falls short of the object in our mind.

However, on the basis of this point it should also be clear that the conclusion *does* apply to this figure, and every other visible triangle inscribed in a semicircle as well, insofar as, and to the extent that, it manages to imitate the properties of the perfect object in our mind. Therefore, the Platonic answer to the question of what this demonstration was about, namely, that it was about a perfect, ideal triangle, which is invisible to the eyes, but is graspable by our understanding, at once provides us with an explanation of the possibility of universal, necessary knowledge. By knowing the properties of the Form or Idea, we know all its particulars, i.e., all the things that imitate it, insofar as they imitate or participate in it. So, the Form itself is a universal entity, a universal model of all its particulars; and since it is the knowledge of this universal entity that can enable us to know at once all its particulars, it is absolutely vital for us to know *what* it is, *what* it is *like*, and exactly *how* it is *related to* its particulars. However, obviously, all these questions presuppose that *it is* at all, namely, that such a universal entity *exists*.

But the existence of such an entity seems to be rather precarious. Consider, for instance, the perfect triangle we were supposed to have in mind during the demonstration of Thales' theorem. If it is a perfect triangle, it obviously has to have three sides, since a perfect triangle has to be a triangle, and nothing can be a triangle unless it has three sides. But of those three sides either at least two are equal or none, that is to say, the

triangle in question has to be either isosceles or scalene (taking ‘isosceles’ broadly, including even equilateral triangles, for the sake of simplicity). However, since it is supposed to be the universal model of *all* triangles, and not only of isosceles triangles, this perfect triangle cannot be an isosceles, and for the same reason it cannot be a scalene triangle either. Therefore, such a universal triangle would have to have inconsistent properties, namely, *both* that it is either isosceles or scalene *and* that it is neither isosceles nor scalene. However, obviously nothing can have these properties at the same time, so nothing can be a universal triangle any more than a round square. So, apparently, no universal triangle can exist. But then, what was our demonstration about? Just a little while ago, we concluded that it could not be directly about any particular triangle (for it was not about the triangle in the figure, and it was even less about any other particular triangle not in the figure), and now we had to conclude that it could not be about a universal triangle either. But are there any further alternatives? It seems obvious that by this demonstration we do gain universal knowledge concerning all particulars. Yet it is also clear that we do not, indeed, we cannot gain this knowledge by examining all particulars, both because they are potentially infinite and because none of them perfectly satisfies the conditions stated in the demonstration. So there must have been something wrong in our characterization of the universal, which compelled us to conclude that, in accordance with that characterization, universals could not exist. Therefore, we are left with a whole bundle of questions concerning the nature and characteristics of universals, questions that cannot be left unanswered if we want to know how universal, necessary knowledge is possible, if at all.

3. The Origin of the Specifically Medieval Problem of Universals

What we may justifiably call the first formulation of “the *medieval* problem of universals” (distinguishing it from the both logically and historically related ancient problems of Plato's Theory of Forms) was precisely such a bundle of questions famously raised by Porphyry in his *Isagoge*, that is, his *Introduction to Aristotle's Categories*. As he wrote:

> (1) Since, Chrysaorius, to teach about Aristotle's *Categories* it is necessary to know what genus and difference are, as well as species, property, and accident, and since reflection on these things is useful for giving definitions, and in general for matters pertaining to division and demonstration, therefore I shall give you a brief account and shall try in a few words, as in the manner of an introduction, to go over what our elders said about these things. I shall abstain from deeper enquiries and aim, as appropriate, at the simpler ones.
>
> (2) For example, I shall beg off saying anything about (a) whether genera and species are real or are situated in bare thoughts alone, (b) whether as real they are bodies or incorporeals, and (c) whether they are separated or in sensibles and have their reality in connection with them. Such business is profound, and requires another, greater investigation. Instead I shall now try to show how the ancients, the Peripatetics among them most of all, interpreted genus and species and the other matters before us in a more logical fashion.[6]

Even though in this way, by relegating them to a “greater investigation”, Porphyry left these questions

unanswered, they certainly proved to be irresistible for his medieval Latin commentators, beginning with Boethius, who produced not just one, but two commentaries on Porphyry's text; the first based on Marius Victorinus's (*fl*. 4th c.) translation, and the second on his own.[7]

In the course of his argument, Boethius makes it quite clear what sort of entity a universal would have to be.

> A universal has to be common to several particulars
>
> 1. in its entirety, and not only in part
> 2. simultaneously, and not in a temporal succession, and
> 3. it should constitute the substance of its particulars.[8]

However, as Boethius argues, nothing in real existence can satisfy these conditions. The main points of his argument can be reconstructed as follows.

Anything that is common to many things in the required manner has to be simultaneously, and as a whole, in the substance of these many things. But these many things are several beings precisely because they are distinct from one another in their being, that is to say, the act of being of the one is distinct from the act of being of the other. However, if the universal constitutes the substance of a particular, then it has to have the same act of being as the particular, because constituting the substance of something means precisely this, namely, sharing the act of being of the thing in question, as the thing's substantial part. But the universal is supposed to constitute the substance of all of its distinct particulars, as a whole, at the same time. Therefore, the one act of being of the universal entity would have to be identical with all the distinct acts of being of its several particulars at the same time, which is impossible.[9]

This argument, therefore, establishes that no one thing can be a universal in its being, that is to say, nothing can be both one being and common to many beings in such a manner that it shares its act of being with those many beings, constituting their substance.

This can easily be visualized in the following diagram, where the tiny lightning bolts indicate the acts of being of the entities involved, namely, a woman, a man, and their universal humanity (the larger dotted figure).

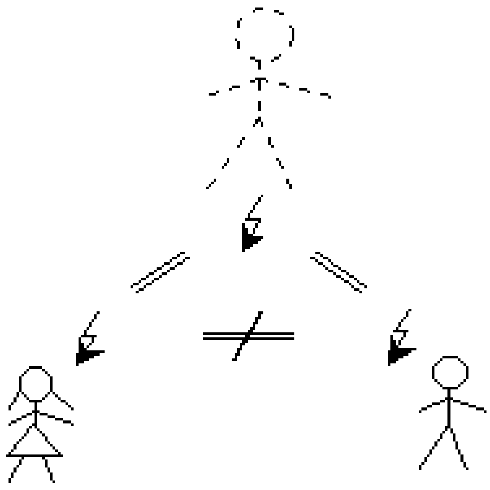

Figure 3. Illustration of the first part of Boethius' argument

But then, Boethius goes on, we should perhaps say that the universal is not one being, but rather many beings, that is, [the collection of][10] those constituents of the individual essences of its particulars on account of which they all fall under the same universal predicable. For example, on this conception, the genus 'animal' would not be some one entity, a universal animality over and above the individual animals, yet somehow sharing its being with them all (since, as we have just seen, that is impossible), but rather [the collection of] the individual animalities of all animals.

Boethius rejects this suggestion on the ground that whenever there are several generically similar entities, they have to have a genus; therefore, just as the individual animals had to have a genus, so too, their individual animalities would have to have another one. However, since the genus of animalities cannot be one entity, some 'super-animality' (for the same reason that the genus of animals could not be one entity, on the basis of the previous argument), it seems that the genus of animalities would have to be a number of further 'super-animalities'. But then again, the same line of reasoning should apply to these 'super-animalities', giving rise to a number of 'super-super-animalities', and so on to infinity, which is absurd. Therefore, we cannot regard the genus as some real being even in the form of [a collection of] several distinct entities. Since similar reasonings would apply to the other Porphyrian predicables as well, no universal can exist in this way.

Now, a universal either exists in reality independently of a mind conceiving of it, or it only exists in the mind. If it exists in reality, then it either has to be one being or several beings. But since it cannot exist in reality in either of these two ways, Boethius concludes that it can only exist in the mind.[11]

However, to complicate matters, it appears that a universal cannot exist in the mind either. For, as Boethius says, the universal existing in the mind is some universal understanding of some thing outside the mind. But then this universal understanding is either disposed in the same way as the thing is, or differently. If it is disposed in the same way, then the thing also has to be universal, and then we end up with the previous problem of a really existing universal. On the other hand, if it is disposed differently, then it is false, for "what is understood otherwise than the thing is is false".[12] But then, all universals in the understanding would have to be false representations of their things; therefore, no universal knowledge would be possible, whereas our considerations started out precisely from the existence of such knowledge, as seems to be clear,

e.g., in the case of geometrical knowledge.

4. Boethius' Aristotelian Solution

Boethius' solution of the problem stated in this form consists in the rejection of this last argument, by pointing out the ambiguity of the principle that “what is understood otherwise than the thing is is false”. For in one sense this principle states the obvious, namely, that an act of understanding that represents a thing *to be* otherwise than the thing is is false. This is precisely the reading of this principle that renders it plausible. However, in another sense this principle would state that an act of understanding which represents the thing in a manner which is different from the manner in which the thing exists is false. In this sense, then, the principle would state that if the mode of representation of the act of understanding is different from the mode of being of the thing, then the act of understanding is false. But this is far from plausible. In general, it is simply not true that a representation can be true or faithful only if the mode of representation matches the mode of being of the thing represented. For example, a written sentence is a true and faithful representation of a spoken sentence, although the written sentence is a visible, spatial sequence of characters, whereas the spoken sentence is an audible, temporal pattern of articulated sounds. So, what exists as an audible pattern of sounds is represented visually, that is, the mode of existence of the thing represented is radically different from the mode of its representation. In the same way, when particular things are represented by a universal act of thought, the things exist in a particular manner, while they are represented in a universal manner, still, this need not imply that the representation is false. But this is precisely the sense of the principle that the objection exploited. Therefore, since in this sense the principle can be rejected, the objection is not conclusive.[13]

However, it still needs to be shown that in the particular case of universal representation the mismatch between the mode of its representation and the mode of being of the thing represented does in fact not entail the falsity of the representation. This can easily be seen if we consider the fact that the falsity of an act of understanding consists in representing something *to be* in a way it is not. That is to say, properly speaking, it is only an act of *judgment* that can be false, by which we think something *to be* somehow. But a *simple* act of understanding, by which we simply understand something without thinking it *to be* somehow, that is, without attributing anything to it, cannot be false. For example, I can be mistaken if I form in my mind the judgment that a man *is* running, whereby I conceive a man *to be* somehow, but if I simply think of a man without attributing either running or not running to him, I certainly cannot make a mistake as to how he *is*.[14] In the same way, I would be mistaken if I were to think that a triangle is neither isosceles nor scalene, but I am certainly not in error if I simply think of a triangle without thinking either that it is isosceles or that it is scalene. Indeed, it is precisely this possibility that allows me to form the universal mental representation, that is, the universal concept of all particular triangles, regardless of whether they are isosceles or scalene. For when I think of a triangle in general, then I certainly do not think of something that is a triangle and is neither isosceles nor scalene, for that is impossible, but I simply think of a triangle, not thinking that it is an isosceles and not thinking that it is a scalene triangle. This is how the mind is able to separate in thought what are inseparable in real existence. Being either isosceles or scalene is inseparable from a triangle in real existence. For it is impossible for something *to be* a triangle, and yet *not to be* an isosceles and *not to be* a scalene triangle either. Still, it is not impossible for something to be *thought to be* a triangle and *not* to be *thought to be* an isosceles and *not* to be *thought to be* a scalene triangle either

(although of course, it still has to be thought to be either isosceles-or-scalene). This separation in thought of those things that cannot be separated in reality is the process of *abstraction*.[15] In general, by means of the process of abstraction, our mind (in particular, the faculty of our mind Aristotle calls *active intellect* (*nous poietikos*, in Greek, *intellectus agens*, in Latin) is able to form universal representations of particular objects by disregarding what distinguishes them, and conceiving of them only in terms of those of their features in respect of which they do not differ from one another.

In this way, therefore, if universals are regarded as universal mental representations existing in the mind, then the contradictions emerging from the Platonic conception no longer pose a threat. On this Aristotelian conception, universals need not be thought of as somehow sharing their being with all their distinct particulars, for their being simply consists in their being thought of, or rather, the particulars' being thought of in a universal manner. This is what Boethius expresses by saying in his final replies to Porphyry's questions the following:

> … genera and species subsist in one way, but are understood in an another. They are incorporeal, but subsist in sensibles, joined to sensibles. They are understood, however, as subsisting by themselves, and as not having their being in others.[16]

But then, if in this way, by positing universals in the mind, the most obvious inconsistencies of Plato's doctrine can be avoided, no wonder that Plato's “original” universals, the universal models which particulars try to imitate by their features, found their place, in accordance with the long-standing Neo-Platonic tradition, in the divine mind.[17] It is this tradition that explains Boethius' cautious formulation of his conclusion concerning Aristotelianism pure and simple, as not providing us with the whole story. As he writes:

> … Plato thinks that genera and species and the rest are not only understood as universals, but also exist and subsist apart from bodies. Aristotle, however, thinks that they are understood as incorporeal and universal, but subsist in sensibles.
>
> I did not regard it as appropriate to decide between their views. For that belongs to a higher philosophy. But we have carefully followed out Aristotle's view here, not because we would recommend it the most, but because this book, [the *Isagoge*], is written about the *Categories*, of which Aristotle is the author.[18]

5. Platonic Forms as Divine Ideas

Besides Boethius, the most important mediator between the Neo-Platonic philosophical tradition and the Christianity of the Medieval Latin West, pointing out also its theological implications, was St. Augustine. In a passage often quoted by medieval authors in their discussions of divine ideas, he writes as follows:

> … in Latin we can call the Ideas “forms” or “species”, in order to appear to translate word for word. But if we call them “reasons”, we depart to be sure from a proper translation - for

> reasons are called “logoi” in Greek, not Ideas - but nevertheless, whoever wants to use this word will not be in conflict with the fact. For Ideas are certain principal, stable and immutable forms or reasons of things. They are not themselves formed, and hence they are eternal and always stand in the same relations, and they are contained in the divine understanding".[19]

As we could see from Boethius' solution, in this way, if Platonic Forms are not universal beings existing in a universal manner, but their universality is due to a universal manner of understanding, we can avoid the contradictions arising from the “naïve” Platonic conception. Nevertheless, placing universal ideas in the divine mind as the archetypes of creation, this conception can still do justice to the Platonic intuition that what accounts for the necessary, universal features of the ephemeral particulars of the visible world is the presence of some universal exemplars in the source of their being. It is precisely in virtue of having some insight into these exemplars themselves that we can have the basis of universal knowledge Plato was looking for. As St. Augustine continues:

> And although they neither arise nor perish, nevertheless everything that is able to arise and perish, and everything that does arise and perish, is said to be formed in accordance with them. Now it is denied that the soul can look upon them, unless it is a rational one, [and even then it can do so] only by that part of itself by which it surpasses [other things] - that is, by its mind and reason, as if by a certain “face”, or by an inner and intelligible “eye”. To be sure, not each and every rational soul in itself, but [only] the one that is holy and pure, that [is the one that] is claimed to be fit for such a vision, that is, the one that keeps that very eye, by which these things are seen, healthy and pure and fair and like the things it means to see. What devout man imbued with true religion, even though he is not yet able to see these things, nevertheless dares to deny, or for that matter fails to profess, that all things that exist, that is, whatever things are contained in their own genus with a certain nature of their own, so that that they might exist, are begotten by God their author, and that by that same author everything that lives is alive, and that the entire safe preservation and the very order of things, by which changing things repeat their temporal courses according to a fixed regimen, are held together and governed by the laws of a supreme God? If this is established and granted, who dares to say that God has set up all things in an irrational manner? Now if it is not correct to say or believe this, it remains that all things are set up by reason, and a man not by the same reason as a horse - for that is absurd to suppose. Therefore, single things are created with their own reasons. But where are we to think these reasons exist, if not in the mind of the creator? For he did not look outside himself, to anything placed [there], in order to set up what he set up. To think that is sacrilege. But if these reasons of all things to be created and [already] created are contained in the divine mind, and [if] there cannot be anything in the divine mind that is not eternal and unchangeable, and [if] Plato calls these principal reasons of things “Ideas”, [then] not only are there Ideas but they are true, because they are eternal and [always] stay the same way, and [are] unchangeable. And whatever exists comes to exist, however it exists, by participation in them. But among the things set up by God, the rational soul surpasses all [others], and is closest to God when it is pure. And to the extent that it clings to God in charity, to that extent, drenched in a certain way and lit up by that intelligible light, it discerns these reasons, not by bodily eyes but by that principal [part] of it by which it surpasses [everything else], that is, by its intelligence. By this vision it becomes most blessed.

> These reasons, as was said, whether it is right to call them Ideas or forms or species or reasons, many are permitted to call [them] whatever they want, but [only] to a very few [is it permitted] to see what is true."[20]

Augustine's conception, then, saves Plato's original intuitions, yet without their inconsistencies, while it also combines his philosophical insights with Christianity. But, as a rule, a really intriguing solution of a philosophical problem usually gives rise to a number of further problems. This solution of the original problem with Plato's Forms is no exception.

Divine Ideas and Divine Simplicity

First of all, it generates a particular ontological/theological problem concerning the relationship between God and His Ideas. For according to the traditional philosophical conception of divine perfection, God's perfection demands that He is absolutely simple, without any composition of any sort of parts.[21] So God and the divine mind are not related to one another as a man and his mind, namely as a substance to one of its several powers, but whatever powers God *has* He *is*. Furthermore, the Divine Ideas themselves cannot be regarded as being somehow the eternal products of the divine mind distinct from the divine mind, and thus from God Himself, for the only eternal being is God, and everything else is His creature. Now, since the Ideas are not creatures, but the archetypes of creatures in God's mind, they cannot be distinct from God. However, as is clear from the passage above, there are several Ideas, and there is only one God. So how can these several Ideas possibly be one and the same God?

Augustine never explicitly raised the problem, but for example Aquinas, who (among others) did, provided the following rather intuitive solution for it.[22] The Divine Ideas are in the Divine Mind as its objects, i.e., as the things understood. But the diversity of the objects of an act of understanding need not diversify the act itself (as when understanding the Pythagorean theorem we understand both squares and triangles). Therefore, it is possible for the self-thinking divine essence to understand itself in a single act of understanding so perfectly that this act of understanding not only understands the divine essence as it is in itself, but also in respect of all possible ways in which it can be imperfectly participated by any finite creature. The cognition of the diversity of these diverse ways of participation accounts for the plurality of divine ideas. But since all these diverse ways are understood in a single eternal act of understanding, which is nothing but the act of divine being, and which in turn is again the divine essence itself, the multiplicity of ideas does not entail any corresponding multiplicity of the divine essence. To be sure, this solution may still give rise to the further questions as to what these diverse ways are, exactly how they are related to the divine essence, and how their diversity is compatible with the unity and simplicity of the ultimate object of divine thought, namely, divine essence itself. In fact, these are questions that were raised and discussed in detail by authors such as Henry of Ghent (c. 1217-1293), Thomas of Sutton (ca. 1250-1315), Duns Scotus (c. 1266-1308) and others.[23]

Illuminationism vs. Abstractionism

Another major issue connected to the doctrine of divine ideas, as should also be clear from the previously quoted passage, was the bundle of epistemological questions involved in Augustine's doctrine of divine

illumination. The doctrine -- according to which the human soul, especially “one that is holy and pure”, obtains a specific supernatural aid in its acts of understanding, by gaining a direct insight into the Divine Ideas themselves -- received philosophical support in terms of a typically Platonic argument in Augustine's *De Libero Arbitrio*.[24] The argument can be reconstructed as follows.

> **The Augustinian Argument for Illumination**.
>
> 1. I can come to know from experience only something that can be found in experience [self-evident]
> 2. Absolute unity cannot be found in experience [assumed]
> 3. Therefore, I cannot come to know absolute unity from experience. [1,2]
> 4. Whatever I know, but I cannot come to know from experience, I came to know from a source that is not in this world of experiences. [self-evident]
> 5. I know absolute unity. [assumed]
> 6. Therefore, I came to know absolute unity from a source that is not in this world of experiences. [3,4,5]
>
> *Proof of 2*. Whatever can be found in experience is some material being, extended in space, and so it has to have a multitude of spatially distinct parts. Therefore, it is many in respect of those parts. But what is many in some respect is not one in that respect, and what is not one in some respect is not absolutely one. Therefore, nothing can be found in experience that is absolutely one, that is, nothing in experience is an absolute unity.
>
> *Proof of 5*. I know that whatever is given in experience has many parts (even if I may not be able to discern those parts by my senses), and so I know that it is not an absolute unity. But I can have this knowledge only if I know absolute unity, namely, something that is not many in any respect, not even in respect of its parts, for, in general, I can know that something is F in a certain respect, and not an F in some other respect, only if I know what it is for something to be an F without any qualification. (For example, I know that the two halves of a body, taken together, are not absolutely two, for taken one by one, they are not absolutely one, since they are also divisible into two halves, etc. But I can know this only because I know that for obtaining absolutely two things [and not just two multitudes of further things], I would have to have two things that in themselves are absolutely one.) Therefore, I know absolute unity.

It is important to notice here that this argument (crucially) assumes that the intellect is passive in acquiring its concepts. According to this assumption, the intellect merely receives the cognition of its objects as it finds them. By contrast, on the Aristotelian conception, the human mind actively processes the information it receives from experience through the senses. So by means of its faculty appropriately called the active or agent intellect, it is able to produce from a limited number of experiences a universal concept equally representing all possible particulars falling under that concept. In his commentary on Aristotle's *De Anima* Aquinas insightfully remarks:

> The reason why Aristotle came to postulate an active intellect was his rejection of Plato's

theory that the essences of sensible things existed apart from matter, in a state of actual intelligibility. For Plato there was clearly no need to posit an active intellect. But Aristotle, who regarded the essences of sensible things as existing in matter with only a potential intelligibility, had to invoke some abstractive principle in the mind itself to render these essences actually intelligible.[25]

On the basis of these and similar considerations, therefore, one may construct a rather plausible Aristotelian counterargument, which is designed to show that we need not necessarily gain our concept of absolute unity from a supernatural source, for it is possible for us to obtain it from experience by means of the active intellect. Of course, similar considerations should apply to other concepts as well.

An Aristotelian-Thomistic counterargument from abstraction.

1. I know from experience everything whose concept my active intellect is able to abstract from experience. [self-evident]
2. But my active intellect is able to abstract from experience the concept of unity, since we all experience each singular thing as being one, distinct from another. [self-evident, common experience][26]
3. Therefore, I know unity from experience by abstraction. [1,2]
4. Whenever I know something from experience by abstraction, I know both the thing whose concept is abstracted and its limiting conditions from which its concept is abstracted. [self-evident]
5. Therefore, I know both unity and its limiting conditions from which its concept is abstracted. [3,4]
6. But whenever I know something and its limiting conditions, and I can conceive of it without its limiting conditions (and this is precisely what happens in abstraction), I can conceive of its absolute, unlimited realization. [self-evident]
7. Therefore, I can conceive of the absolute, unlimited realization of unity, based on the concept of unity I acquired from experience by abstraction. [5,6]
8. Therefore, it is not necessary for me to have a preliminary knowledge of absolute unity before all experience, from a source other than this world of experiences. [7]

To be sure, we should notice here that this argument *does not falsify the doctrine* of illumination. Provided it works, it only *invalidates* the Augustinian-Platonic *argument* for illumination. Furthermore, this is obviously not a sweeping, knock-down refutation of the idea that at least some of our concepts perhaps could not so simply be derived from experience by abstraction; in fact, in the particular case of unity, and in general, in connection with our transcendental notions (i.e., notions that apply in each Aristotelian category, so they *transcend* the limits of each one of them, such as the notions of *being*, *unity*, *goodness*, *truth*, etc.), even the otherwise consistently Aristotelian Aquinas would have a more complicated story to tell.[27] Nevertheless, although Aquinas would still leave some room for illumination in his epistemology, he would provide for illumination an entirely naturalistic interpretation, as far as the acquisition of our intellectual concepts of material things is concerned, by simply identifying it with the “intellectual light in us”, that is, the active intellect, which enables us to acquire these concepts from experience by abstraction.[28] Duns

Scotus, who opposed Aquinas on so many other points, takes basically the same stance on this issue. Other medieval theologians, especially such prominent "Augustinians" as Bonaventure, Matthew of Aquasparta, or Henry of Ghent, would provide greater room for illumination in the form of a direct, specific, supernatural influence needed for human intellectual cognition in this life besides the general divine cooperation needed for the workings of our natural powers, in particular, the abstractive function of the active intellect.[29]

In general, illuminationism and abstractionism were never treated by medieval thinkers as mutually exclusive alternatives. They rather served as the two poles of a balancing act in judging the respective roles of nature and direct divine intervention in human intellectual cognition.[30]

Although Platonism definitely survived throughout the Middle Ages (and beyond), in the guise of the interconnected doctrines of divine ideas, participation, and illumination, there was a quite general Aristotelian consensus,[31] especially after Abelard's time, that the mundane universals of the species and genera of material beings exist as such *in the human mind*, as a result of the mind's abstracting from their individuating conditions. But consensus concerning this much by no means entailed a unanimous agreement on exactly what the universals thus abstracted are, what it is for them to exist in the mind, how they are related to their particulars, what their real foundation in those particulars is, what their role is in the constitution of our universal knowledge, and how they contribute to the encoding and communication of this knowledge in the various human languages. For although the general Aristotelian stance towards universals successfully handles the inconsistencies quite obviously generated by a naïve Platonist ontology, it gives rise precisely to these further problems of its own.

6. Universals According to Abelard's Aristotelian Conception

It was Abelard who first dealt with the problem of universals explicitly in this form. Having relatively easily disposed of putative universal forms as real entities corresponding to Boethius' definition, in his *Logica Ingredientibus* he concludes that given Aristotle's definition of universals in his *On Interpretation* as those things that can be predicated of several things, it is only universal *words* that can be regarded as really existing universals. However, since according to Aristotle's account in the same work, words are meaningful in virtue of signifying concepts in the mind, Abelard soon arrives at the following questions:

1. What is the *common cause* in accordance with which a common name is imposed?
2. What is the understanding's *common conception* of the likeness of things?
3. Is a word called "common" on account of the common cause things agree in, or on account of the common conception, or on account of both together?[32]

These questions open up a new chapter in the history of the problem of universals. For these questions add a new aspect to the bundle of the originally primarily ontological, epistemological, and theological questions constituting the problem, namely, they add a *semantic* aspect. On the Aristotelian conception of universals as universal *predicables*, there obviously *are* universals, namely, our universal words. But the universality

of our words is clearly not dependent on the physical qualities of our articulate sounds, or of the various written marks indicating them, but on their representative function. So, to give an account of the universality of our universal words, we have to be able to tell in virtue of what they have this universal representative function, that is to say, we have to be able to assign a *common cause* by the recognition of which in terms of a *common concept* we can give a *common name* to a *potential infinity of individuals* belonging to the same kind.

But this common cause certainly cannot be a *common thing* in the way Boethius described universal things, for, as we have seen, the assumption of the existence of such a common thing leads to contradictions. To be sure, Abelard also provides a number of further arguments, dealing with several refinements of Boethius' characterization of universals proposed by his contemporaries, such as William of Champeaux, Bernard of Chartres, Clarembald of Arras, Jocelin of Soissons, and Walter of Mortagne – but I cannot go into those details here.[33] The point is that he refutes and rejects all these suggestions to save real universals either as common things, having their own real unity, or as collections of several things, having a merely collective unity. The gist of his arguments against the former view is that the universal thing on that view would have to have its own numerical unity, and therefore, since it constitutes the substance of all its singulars, all these singulars would have to be substantially one and the same thing which would have to have all their contrary properties at the same time, which is impossible. The main thrust of his arguments against the collection-theory is that collections are arbitrary integral wholes of the individuals that make them up, so they simply do not fill the bill of the Porphyrian characterizations of the essential predicables such as genera and species.[34]

So, the common cause of the imposition of universal words cannot be any one thing, or a multitude of things; yet, being a common *cause*, it cannot be nothing. Therefore, this common cause, which Abelard calls the *status*[35] of those things to which it is common, is a cause, but it is a cause which is a non-thing. However strange this may sound, Abelard observes that sometimes we do assign *causes* which are not *things*. For example, when we say “The ship was wrecked because the pilot was absent”, the cause that we assign, namely, that the pilot was absent is not some *thing*, it is rather *how* things were, i.e., the *way* things were, which in this case we signify by the whole proposition “The pilot was absent”.[36] From the point of view of understanding what Abelard's *status* are, it is significant that he assimilates the causal role of *status* as the common cause of imposition to causes that are signified by whole propositions. These *significata* of whole propositions, which in English we may refer to by using the corresponding “that-clauses” (as I did above, referring to the cause of the ship's wreck by the phrase “that the pilot was absent”), and in Latin by an accusative-with-infinitive construction, are what Abelard calls the *dicta* of propositions. These *dicta*, not being identifiable with any single thing, yet, not being nothing, constitute an ontological realm that is completely different from that of ordinary things. But it is also in this realm that Abelard's *common causes of imposition* may find their place.

Abelard says that the common cause of imposition of a universal name has to be something in which things falling under that name agree. For example, the name ‘man’ (in the sense of ‘human being’, and not in the sense of ‘male human being’) is imposed on all humans on account of something in which all humans, as such, agree. But that in which all humans as such agree is that each one of them is a man, that is, each one agrees with all others in their *being a man*. So it is their being human [*esse hominem*] that is the common cause Abelard was looking for, and this is what he calls the *status* of man. The *status* of man is not a thing;

it is not any singular man, for obviously no singular man is common to all men, and it is not a universal man, for there is no such a thing. But *being a man* is common in the required manner (i.e., it is something in which all humans agree), yet it is clearly not a thing. For let us consider the singular propositions ‘Socrates is a man’ [*Socrates est homo*], ‘Plato is a man’ [*Plato est homo*], etc. These signify their *dicta*, namely, Socrates's being a man [*Socratem esse hominem*], and Plato's being a man [*Platonem esse hominem*], etc. But then it is clear that if we abstract from the singular subjects and retain what is common to them all, we can get precisely the *status* in which all these subjects agree, namely, being a man [*esse hominem*]. So the *status*, just like the *dicta* from which they can be obtained, constitute an ontological realm that is entirely different from that of ordinary things.

Still, despite the fact that it clearly has to do something with abstraction, an activity of the mind, Abelard insists that a *status* is not a concept of our mind. The reason for his insistence is that the *status*, being the *common cause* of imposition of a common name, has to be something real, the existence of which is not dependent on the activity of our minds. A *status* is there in the nature of things, regardless of whether we form a mental act whereby we recognize it or not. In fact, for Abelard, a *status* is an object of the divine mind, whereby God preconceives the state of his creation from eternity.[37] A concept, or mental image *of our mind*, however, exists as the object of our mind only insofar as our mind performs the mental act whereby it forms this object. But this object, again, is not a thing, indeed, not any more than any other fictitious object of our minds. However, what distinguishes the *universal concept* from a merely *fictitious object* of our mind is that the former corresponds to a *status* of really existing singular things, whereas the latter does not have anything corresponding to it.

To be sure, there are a number of points left in obscurity by Abelard's discussion concerning the relationships of the items distinguished here. For example, Abelard says that we cannot conceive of the *status*. However, it seems that we can only signify by our words whatever we can conceive. Yet, Abelard insists that besides our concepts, our words *must* signify the *status* themselves.[38] A solution to the problem is only hinted at in Abelard's remark that the names can signify *status*, because“their inventor *meant* to impose them in accordance with certain natures or characteristics of things, even if he did not know how to think out the nature or characteristic of the thing”.[39] So, we may assume that although the inventor of the name does not know the *status*, his vague, “senses-bound” conception, *from which* he takes his word's signification, is directed at the *status*, as to *that which* he *intends* to signify.[40] However, Abelard does not work out this suggestion in any further detail. Again, it is unclear how the *status* is related to the individualized natures of the things that agree in the *status*. If the *status* is what the divine mind conceives of the singulars in abstraction from them, why couldn't the nature itself be conceived in the same way? – after all, the abstract nature would not have to be a thing any more than a *status* is, for its existence would not be *real being*, but merely its *being conceived*. Furthermore, it seems quite plausible that Abelard's *status* could be derived by abstraction from singular *dicta* with the same predicate, as suggested above. But *dicta* are the quite ordinary *significata* of *our* propositions, which Abelard never treats as epistemologically problematic, so why would the *status*, which we could apparently abstract from them, be accessible only to the divine mind?

I'm not suggesting that Abelard could not provide acceptable and coherent answers to these and similar questions and problems.[41] But perhaps these problems also contributed to the fact that by the 13th century his doctrine of *status* was no longer in currency. Another historical factor that may have contributed to the

waning of Abelard's theory was probably the influence of the newly translated Aristotelian writings along with the Arabic commentaries that flooded the Latin West in the second half of the 12th century.

7. Universal Natures in Singular Beings and in Singular Minds

The most important influence in this period from our point of view came from Avicenna's doctrine distinguishing the absolute consideration of a universal nature from what applies to the same nature in the subject in which it exists. The distinction is neatly summarized in the following passage.

> Horsehood, to be sure, has a definition that does not demand universality. Rather it is that to which universality happens. Hence horsehood itself is nothing but horsehood only. For in itself it is neither many nor one, neither is it existent in these sensibles nor in the soul, neither is it any of these things potentially or actually in such a way that this is contained under the definition of horsehood. Rather [in itself it consists] of what is horsehood only.[42]

In his little treatise *On Being and Essence*,Aquinas explains the distinction in greater detail in the following words:

> A nature, however, or essence …can be considered in two ways. First, we can consider it according to its proper notion, and this is its absolute consideration; and in this way nothing is true of it except what pertains to it as such; whence if anything else is attributed to it, that will yield a false attribution. …In the other way [an essence] is considered as it exists in this or that [individual]; and in this way something is predicated of it *per accidens* [non-essentially], on account of that in which it exists, as when we say that a man is white because Socrates is white, although this does not pertain to man as such.
>
> A nature considered in this way, however, has two sorts of existence. It exists in singulars on the one hand, and in the soul on the other, and from each of these [sorts of existence] it acquires accidents. In the singulars, furthermore, the essence has several [acts of] existence according to the multiplicity of singulars. Nevertheless, if we consider the essence in the first, or absolute, sense, none of these pertain to it. For it is false to say that the essence of man, considered absolutely, has existence in this singular, because if existence in this singular pertained to man insofar as he is man, man would never exist, except as this singular. Similarly, if it pertained to man insofar as he is man not to exist in this singular, then the essence would never exist in the singular. But it is true to say that man, but not insofar as he is man, may be in this singular or in that one, or else in the soul. Therefore, the nature of man considered absolutely abstracts from every existence, though it does not exclude any. And the nature thus considered is what is predicated of each individual.[43]

So, a common nature or essence according to its absolute consideration abstracts from all existence, both in the singulars and in the mind. Yet, and this is the important point, it is *the same* nature that informs both the

singulars that have this nature and the minds conceiving of them in terms of this nature. To be sure, this sameness is not numerical sameness, and thus it does not yield numerically one nature. On the contrary, it is the sameness of several, numerically distinct realizations of the same information-content, just like the sameness of a book in its several copies. Just as there is no such a thing as a universal book over and above the singular copies of the same book, so there is no such a thing as a universal nature existing over and above the singular things of the same nature; still, just as it is true to say that the singular copies are the copies of *the same book*, so it is true to say that these singulars are of *the same nature*.

Indeed, this analogy also shows why this conception should be so appealing from the point of view of the original epistemological problem of the possibility of universal knowledge, without entailing the ontological problems of naïve Platonism. For just as we do not need to read all copies of the same book in order to know what we can find on the same page in the next copy (provided it is not a corrupt copy),[44] so we can know what may apply to all singulars of the same nature without having to experience them all. Still, we need not assume that we can have this knowledge only if we can get somehow in a mysterious contact with the universal nature over and above the singulars; all we need is to learn how “to read” the singulars in our experience to discern the “common message”, the universal nature, informing them all, uniformly, yet in their distinct singularity. (Note that “reading the singulars” is not a mere metaphor: this is precisely what geneticists are quite literally doing in the process of gene sequencing, for instance, in the human genome project.) Therefore, the *same nature* is not *the same* in the same way as the *same individual* having this nature is the same as long as it exists. For that *same nature*, insofar as it is regarded as *the same*, does not even exist at all; it is said to be the same only insofar as it is *recognizable as the same*, if we disregard everything that distinguishes its instances in several singulars. (Note here that whoever would want to deny such a *recognizable sameness* in and across several singulars would have to deny that he is able to recognize the same words or the same letters in various sentences; so such a person would not be able to read, write, or even to speak, or understand human speech. But then we shouldn't really worry about such a person in a philosophical debate.)

However, at this point some further questions emerge. If this common nature is *recognizably the same* on account of disregarding its individuating conditions in the singulars, then isn't it the result of abstraction; and if so, isn't it in the abstractive mind as its object? But if it is, then how can Aquinas say that it abstracts *both* from being in the singulars *and* from being in the mind?

Here we should carefully distinguish between what we can say about *the same nature as such*, and what we can say about *the same nature on account of its conditions* as it exists in this or that subject. Again, using our analogy, we can certainly consistently say that the same book in its first edition was 200 pages, whereas in the second only 100, because it was printed on larger pages, but the book itself, as such, is neither 200 nor 100 pages, although it can be either. In the same way, we can consistently say that *the same nature as such* is neither in the singulars nor in the mind, but of course it is only insofar as it is in the mind that it can be *recognizably the same*, on account of the mind's abstraction. Therefore, that it is abstract and is actually recognized as the same in its many instances is something that belongs to the same nature only on account of being conceived by the abstractive mind. This is the reason why the nature is called a *universal concept*, insofar as it is in the mind. Indeed, it is only under this aspect that it is properly called a universal. So, although *that which is predicable* of several singulars is nothing but the common nature as such, considered absolutely, still, *that it is predicable* pertains to the same nature only on account of being conceived by the

abstractive intellect, insofar as it is a concept of the mind.

At any rate, this is how Aquinas solves the paralogism that seems to arise from this account, according to which the true claims that Socrates is a man and man is a species would seem to entail the falsity that Socrates is a species. For if we say that in the proposition ‘Socrates is a man’ the predicate signifies human nature absolutely, but the same nature, on account of its abstract character, is a species, the false conclusion seems inevitable.[45]

However, since the common nature is not a species in its absolute consideration, but only insofar as it is in the mind, the conclusion does not follow. Indeed, this reasoning would be just as invalid as the one trying to prove that this book, pointing to the second edition which is actually 100 pages, is 200 pages, because the same book was 200 hundred pages in its first edition. For just as its being 200 pages belongs to the same book only in its first edition, so its being a species belongs to human nature only as it exists in the mind.

Nevertheless, even though this solution works, the emergence of the paralogism itself, and the complexities involved in explaining it away, show the inherent difficulties of this account. The main difficulty is the trouble of keeping track of what we are talking about, when it becomes crucial to know what pertains to what on account of what; in general, when the conditions of identity and distinction of the items we are talking about become variable and occasionally rather unclear.

Indeed, we can appreciate just how acute these difficulties may become if we survey the items that needed to be distinguished in what may be described as the common conceptual framework of the “realist” *via antiqua*, the “old way” of doing philosophy and theology, before the emergence of the “modern way”, the “nominalist” *via moderna* challenging some fundamental principles of the older framework, resulting mostly from the semantic innovations introduced by William Ockham. The survey of these items and the problems they generate will then allow us to see in greater detail the main motivation for Ockham's innovations.

8. Universals in the *Via Antiqua*

In this framework, we have first of all the universal or common terms of spoken and written languages, which are common on account of being imposed upon universal concepts of the human mind. The concepts themselves are universal on account of being obtained by the activity of the abstractive human mind from experiences of singulars. But the process of concept formation also involves various stages.

In the first place, the sensory information collected by the single senses is distinguished, synthesized, and collated by the higher sensory faculties of the common sense [*sensus communis*] and the so-called cogitative power [*vis cogitativa*], to be stored in sensory memory as *phantasms*, the sensory representations of singulars in their singularity. The active intellect [*intellectus agens*] uses this sensory information to extract its intelligible content and produce the intelligible species [*species intelligibiles*], the universal representations of several individuals in their various degrees of formal unity, disregarding their distinctive features and individuating conditions in the process of abstraction.

The intelligible species are stored in the intellectual memory of the potential intellect [*intellectus possibilis*], which can then use them to form the corresponding concept in an act of thought, for example, in forming a judgment. The intelligible species and the concepts themselves, being formed by individual human minds, are individual in their being, insofar as they pertain to this or that human mind. However, since they are the result of abstraction, in their information content they are universal.

Now insofar as this universal information content is common to all minds that form these concepts at all, and therefore it is a common intelligible content gained by these minds from their objects insofar as they are conceived by these minds in a universal manner, later scholastic thinkers refer to it as the objective concept [*conceptus obiectivus*], distinguishing it from the formal or subjective concepts [*conceptus formales seu subiectivi*], which are the individual acts of individual minds carrying this information (just as the individual copies of a book carry the information content of the book).[46] It is this objective concept that is identified as the universal of the human mind (distinguished from the universals of the divine mind), namely, a species, a genus, a difference, a property, or an accident. (Note that these are only the simple concepts. Complex concepts, such as those corresponding to complex terms and propositions are the products of the potential intellect using these concepts in its further operations.)

These universals, then, as the objective concepts of the mind, would be classified as beings of reason [*entia rationis*], the being of which consists in their being conceived.[47] To be sure, they are not merely fictitious objects, for they are grounded in the nature of things insofar as they carry the universal information content abstracted from the singulars. But then again, the universal information content of the objective concept itself, considered not insofar as it is in the mind as its object, but in itself, disregarding whatever may carry it, is distinguished from its carriers both in the mind and in the ultimate objects of the mind, the singular things, as the nature of these things in its absolute consideration.

However, the common nature as such cannot exist on its own any more than a book could exist without any copies of it or any minds conceiving of it. So, this common nature has real existence only in the singulars, informing them, and giving them their recognizably common characteristics. However, these common characteristics can be recognized as such only by a mind capable of abstracting the common nature from experiencing it in its really existing singular instances. But it is on account of the real existence of these individualized instances in the singulars that the common nature can truly be predicated of the singulars, as long as they are actually informed by these individualized instances.

The items thus distinguished and their interconnections can be represented by the following block-diagram. The dashed frames indicate that the items enclosed by them have a certain reduced ontological status, a "diminished" mode of being, while the boxes partly sharing a side indicate the (possible) partial identities of the items they enclose.[48] The arrows pointing from the common term to the singulars, their individualized natures and items in the mind on this diagram represent semantic relations, which I am going to explain later, in connection with Ockham's innovations. The rest of the arrows indicate the flow of information from experience of singulars through the sensory faculties to the abstractive mind, and to the application of the universal information abstracted by the mind to further singular experiences in acts of judgment.

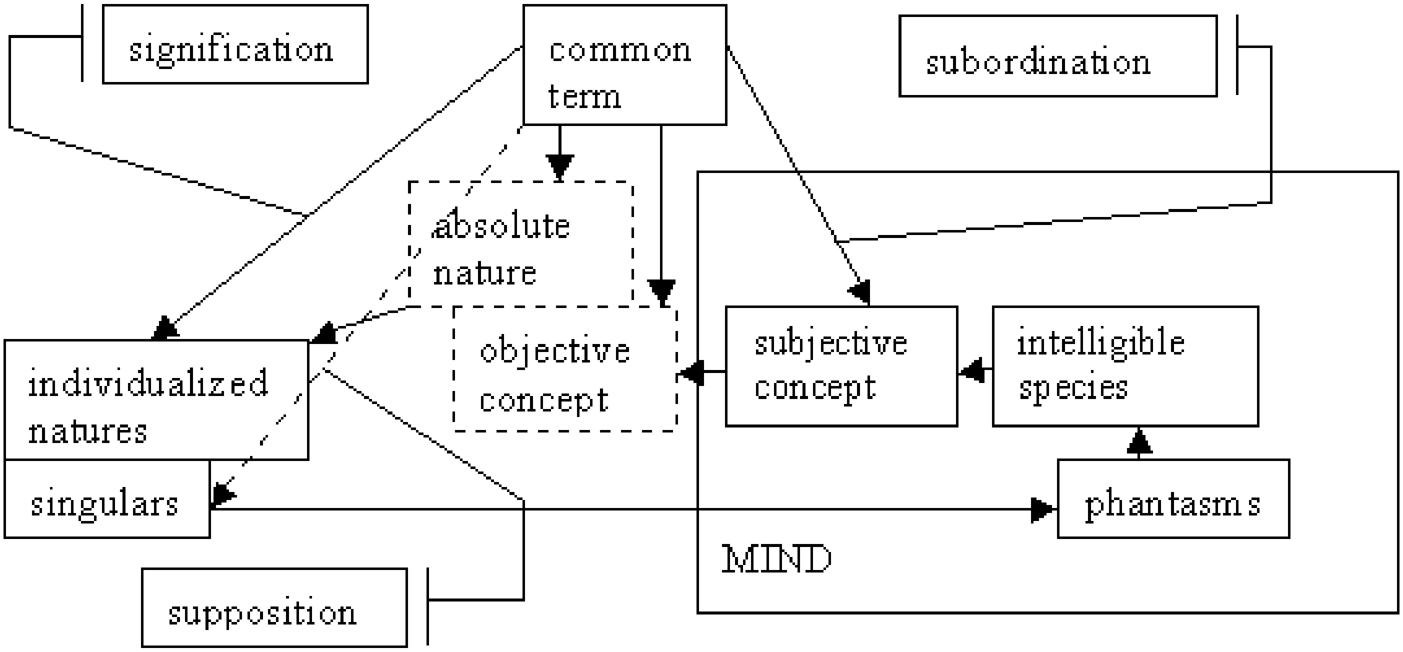

Figure 4. The *via antiqua* conception

Obviously, this is a rather complicated picture. However, its complexity itself should not be regarded as problematic or even surprising, for that matter. After all, this diagram merely summarizes, and distinguishes the main stages of, how the human mind processes the intelligible, universal information received from a multitude of singular experiences, and then again, how it applies this information in classifying further experiences. This process may reasonably be expected to be complex, and should not be expected to involve fewer stages than, e.g., setting up, and retrieving information from, a computer database.

What renders this picture more problematic is rather the difficulties involved in identifying and distinguishing these stages and the corresponding items. Further complications were also generated by the variations in terminology among several authors, and the various criteria of identity and distinctness applied by them in introducing various different notions of identity and distinctness. In fact, many of the great debates of the authors working within this framework can be characterized precisely as disputing the identity or distinctness of the items featured here, or the very criteria of identifying or distinguishing them.

For example, already Abelard raised the question whether the concept or mental image, which we may identify in the diagram as the objective concept of later authors, should be identified with the act of thought, which we may identify as the subjective concept, or perhaps a further act of the mind, called *formatio*, namely, the potential intellect's act of forming the concept, using the intelligible species as the principle of its action. Such distinctions were later on severely criticized by authors such as John Peter Olivi and others, who argued for the elimination of intelligible species, and, in general, of any intermediaries between an act of the intellect and its ultimate objects, the singulars conceived in a universal manner.[49]

Again, looking at the diagram on the side of the singulars, most 13th century authors agreed that what accounts for the specific unity of several individuals of the same species, namely, their specific nature, should be something other than what accounts for their numerical distinctness, namely, their principle of individuation. However, one singular entity in a species of several co-specific individuals has to contain

both the principle of the specific unity of these individuals and its own principle of individuation. Therefore, this singular entity, being a composite at least of its specific nature and its principle of individuation, has to be distinct from its specific nature. At any rate, this is the situation with material substances, whose principle of individuation was held to be their matter. However, based on this reasoning, immaterial substances, such as angels, could not be regarded as numerically distinct on account of their matter, but only on account of their form. But since form is the principle of specific unity, difference in form causes specific diversity. Therefore, on this basis, any two angels had to be regarded as different in species. This conclusion was explicitly drawn by Aquinas and others, but it was rejected by Augustinian theologians, and it was condemned in Paris in 1277.[50]

So, no wonder authors such as Henry of Ghent and Duns Scotus worked out alternative accounts of individuation, introducing not only different principles of individuation, such as the Scotists' famous (or infamous) *haecceity*, but also different criteria of distinctness and identity, such as those grounding Henry of Ghent's *intentional distinction*, or Scotus's *formal distinction*,[51] or even later Suarez' *modal distinction*.[52]

But even further problems arose from considering the identity or distinctness of the individualized natures signified by several common terms in one and the same individual. The metaphysical debate over the real distinction of essence and existence from this point of view is nothing but the issue whether the individualized common nature signified by the definition of a thing is the same as the act of being signified by the verb ‘is’ in the same thing. In fact, the famous problem of the plurality vs. unity of substantial forms may also be regarded as a dispute over whether the common natures signified by the substantial predicates on the Porphyrian tree in the category of substance are distinct or the same in the same individual.[53] Finally, and this appears to be the primary motivation for Ockham's innovations, there was the question whether one has to regard all individualized common natures signified in the same individual by several predicates in the ten Aristotelian categories as distinct from one another. For the affirmative answer would involve commitment to a virtually limitless multiplication of entities.

Indeed, according to Ockham, the *via antiqua* conception would entail that

> a column is to the right by to-the-rightness, God is creating by creation, is good by goodness, just by justice, mighty by might, an accident inheres by inherence, a subject is subjected by subjection, the apt is apt by aptitude, a chimera is nothing by nothingness, someone blind is blind by blindness, a body is mobile by mobility, and so on for other, innumerable cases.[54]

And this is nothing, but “multiplying beings according to the multiplicity of terms... which, however, is erroneous and leads far away from the truth”.[55]

9. Universals in the *Via Moderna*

To be sure, as the very debates within the *via antiqua* framework concerning the identity or non-identity of various items distinguished in that framework indicate, Ockham's charges are not quite justified.[56] After all, several *via antiqua* authors *did* allow the identification of the *significata* of terms belonging to various

categories, so their “multiplication of beings” did not necessarily match the multiplicity of terms. Furthermore, since *via antiqua* authors also distinguished between various modes or senses of being, allowing various sorts of “diminished” kinds of being, such as *beings of reason*, their ontological commitments were certainly not as unambiguous as Ockham would have us believe in this passage. However, if we contrast the diagram of the *via antiqua* framework above with the following schematic representation of the *via moderna* framework introduced by Ockham, we can immediately appreciate the point of Ockham's innovations.

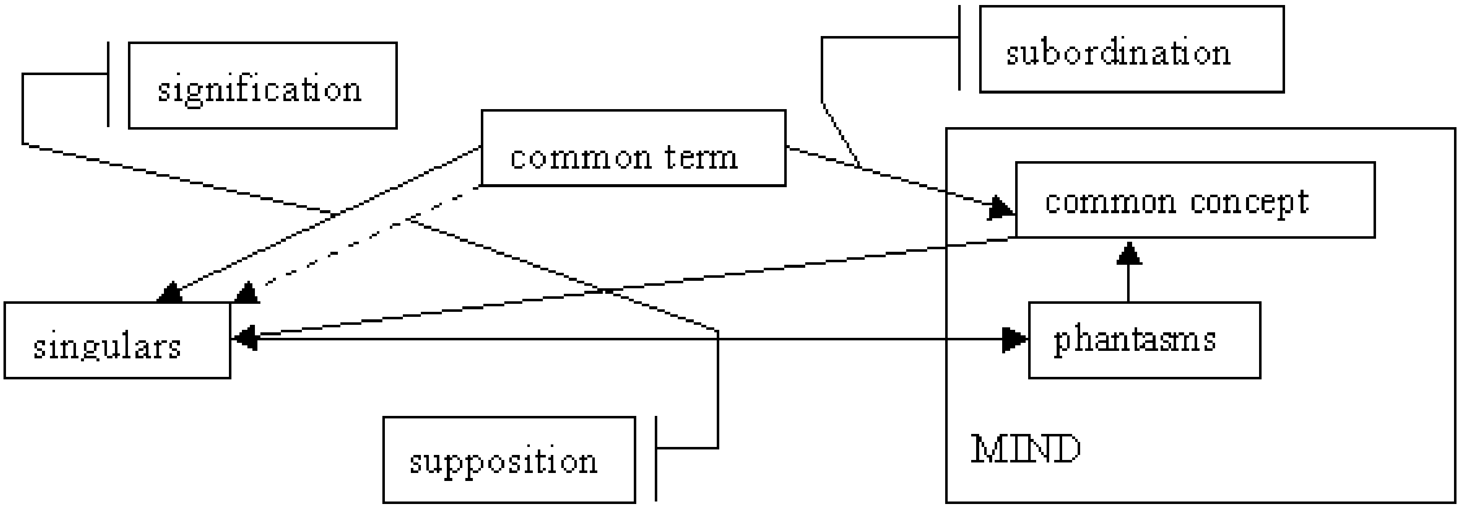

Figure 5. The *via moderna* conception

Without a doubt, it is the captivating simplicity of this picture, especially as compared with the complexity of the *via antiqua* picture, that was the major appeal of the Ockhamist approach. There are fewer items here, equally on the same ontological footing, distinguished from one another in terms of the same unambiguous distinction, the numerical distinction between individual real entities.

To be sure, there still are universals in this picture. But these universals are neither common natures “contracted” to individuals by some really or merely formally distinct principle of individuation, nor some universal objects of the mind, which exist in a “diminished” manner, as *beings of reason*. Ockham's universals, at least in his mature theory,[57] are just our common terms and our common concepts. Our common terms, which are just singular utterances or inscriptions, are common in virtue of being subordinated to our common concepts. Our common concepts, on the other hand, are just singular acts of our singular minds. Their universality consists simply in the universality of their representative function. For example, the common term ‘man’ is a spoken or written universal term of English, because it is subordinated to that concept of our minds by which we conceive of each man indifferently. It is this indifference in its representative function that enables the singular act of my mind to conceive of each man in a universal manner, and the same goes for the singular act of your mind. Accordingly, there is no need to assume that there is anything in the individual humans, distinct from these humans themselves, a common yet individualized nature waiting to be abstracted by the mind. All we need to assume is that two humans are more similar to each other than either of them to a brute animal, and all animals are more similar to each other than any of them to a plant, etc., and that the mind, being able to recognize this similarity, is able to represent the humans by means of a common specific concept, the animals by means of a common generic

concept, all living things by means of a more general generic concept, etc.[58] In this way, then, the common terms subordinated to these concepts need not signify some abstract common nature in the mind, and consequently its individualized instances in the singulars, for they directly signify the singulars themselves, just as they are directly conceived by the universally representative acts of the mind. So, what these common terms signify are just the singulars themselves, which are also the things referred to by these terms when they are used in propositions. Using the customary rendering of the medieval logical terminology, the things ultimately signified by a common term are its *significata*, while the things referred to by the same term when it is used in a proposition are their (personal) *supposita*.[59]

Now if we compare the two diagrams representing the respective conceptions of the two *viae*, we can see just how radically Ockham's innovations changed the character of the semantic relations connecting terms, concepts and things. In both *viae*, common terms are subordinated to common concepts, and it is in virtue of this subordination that they ultimately signify what their concepts represent. In the *via moderna*, a concept is just an act of the mind representing singulars in a more or less indifferent manner, yielding a more or less universal signification for the term. In the *via antiqua*, however, the act of the mind is just one item in a whole series of intermediary representations, distinguished in terms of their different functions in processing universal information, and connected by their common content, ultimately representing the common, yet individualized natures of their singulars.[60] Accordingly, a common term, expressing this common content, is primarily subordinated to the objective concept of the mind. But of course this objective concept is only the common content of the singular representative acts of singular minds, their subjective concepts, formed by means of the intelligible species, abstracted by their active intellects. On the other hand, the objective concept, abstracting from all individuating conditions, expresses only what is common to all singulars, namely, their nature considered absolutely. But this absolutely considered nature is only the common content of what informs each singular of the same nature in its actual real existence. So the term's ultimate *significata* will have to be the individualized natures of the singulars. But these ultimate *significata* may still not be the singulars themselves, namely, when the things informed by these *significata* are not metaphysically simple. In the *via moderna* conception, therefore, the ultimate *significata* of a term are nothing but those singular things that can be the term's *supposita* in various propositions, as a matter of semantics. By contrast, in the *via antiqua* conception, a term's ultimate *significata* may or may not be the same things as the term's (personal) *supposita*, depending on the constitution of these *supposita*, as a matter of metaphysics. The singulars will be the *supposita* of the term when it is used as the subject term of a proposition in which something is predicated about the things informed by these ultimate *significata* (in the case of metaphysically simple entities, the term's *significata* and *supposita* coincide).[61]

Nevertheless, despite the nominalists' charges to the contrary, the *via antiqua* framework, as far as its semantic considerations are concerned, was no more committed to the real distinction of the *significata* and *supposita* of its common terms than the *via moderna* framework was. For if the semantic theory in itself had precluded the identification of these semantic values, then the question of possible identity of these values could not have been meaningfully raised in the first place. Furthermore, in that case such identifications would have been precluded as meaningless even when talking about metaphysically simple entities, such as angels and God, whereas the metaphysical simplicity of these entities was expressed precisely in terms of such identifications. But also in the mundane cases of the *significata* and *supposita* of concrete and abstract universal terms in the nine accidental categories, several *via antiqua* authors argued for the identification of these semantic values both within and across categories. First of all there was Aristotle's authority for the

claim that action and passion are the same motion,[62] so the significata of terms in these two categories could not be regarded as really distinct entities. But several authors also argued for the identification of relations with their foundations, that is to say, for the identity of the significata of relative terms with the significata of terms in the categories quantity and quality. (For example, on this conception, my equality in height to you would be just my height, provided you were of the same height, and not a distinct "equality-thing" somehow attached to my height, caused by our equal heights.)[63]

By contrast, what makes the *via moderna* approach simpler is that it "automatically" achieves such identifications already on the basis of its semantic principles. Since in this approach the *significata* of concrete common terms are just the singulars directly represented by the corresponding concepts, the *significata* and (personal) *supposita* of terms are taken to be the same singulars from the beginning. So these common terms *signify* and *supposit* for the same things either absolutely, provided the term is *absolute*, or in relation to other singulars, provided the term is *connotative*. But even in the case of connotative terms, such as relative terms (in fact, all terms in the nine accidental categories, except for some abstract terms in the category quality, according to Ockham) we do not need to assume the existence of some mysterious relational entities informing singular substances. For example, the term 'father' need not be construed as signifying in me an inherent relation, my fatherhood, somehow connecting me to my son, and suppositing for me on that account in the context of a proposition; rather, it should merely be construed as signifying me in relation to my son, thereby suppositing for me in the context of a proposition, while connoting my son.

10. The Separation of the *viae*, and the Breakdown of Scholastic Discourse in Late-Medieval Philosophy

The appeal of the simplicity of the *via moderna* approach, especially as it was systematically articulated in the works of John Buridan and his students, had a tremendous impact on late-medieval philosophy and theology. To be sure, many late-medieval scholars, who were familiar with both ways, would have shared the sentiment expressed by the remark of Domingo Soto (1494-1560, describing himself as someone who was "born among nominalists and raised by realists")[64] to the effect that whereas the realist doctrine of the *via antiqua* was more difficult to understand, still, the nominalist doctrine of the *via moderna* was more difficult to believe.[65] Nevertheless, the overall simplicity and internal consistency of the nominalist approach were undeniable, gathering a strong following by the 15th century in all major universities of Europe, old and newly established alike.[66]

The resulting separation and the ensuing struggle of the medieval *viae* did not end with the victory of the one over the other. Instead, due to the primarily *semantic* nature of the separation, getting the parties embroiled in increasingly complicated ways of talking past each other, thereby generating an ever growing dissatisfaction, even contempt, in a new, lay, humanist intelligentsia,[67] it ended with the demise of the characteristically medieval conceptual frameworks of both *viae* in the late-medieval and early modern period.

These developments, therefore, also put an end to the specifically *medieval* problem of universals. However, the increasingly rarified late-medieval problem eventually vanished only to give way to several modern

variants of *recognizably the same* problem, which keeps recurring in one form or another in contemporary philosophy as well. Indeed, one may safely assert that as long as there is interest in the questions of how a human language obviously abounding in universal terms can be meaningfully mapped onto a world of singulars, there *is* a problem of universals, regardless of the details of the particular conceptual framework in which the relevant questions are articulated. Clearly, in this sense, the problem of universals is itself a universal, the universal problem of accounting for the relationships between mind, language, and reality.

Stanford Encyclopedia of Philosophy
Notes to Medieval Theories of Universals

Notes

1. In a somewhat free translation: “I like Plato, but I like the truth even more.” Cf. Aristotle, *The Nicomachean Ethics*, 1096a15, in *The Complete Works of Aristotle*.

2. These are the opposing, yet complementary attitudes (universals come “from above”, for Plato, and “from below”, for Aristotle) that are famously immortalized in the gestures of the two philosophers in the center of Raphael's picture “The School of Athens”.

3. To be sure, there were medieval authors who were skeptical about the reconcilability of Plato and Aristotle on the issue of universals. Cf. the following remark by John of Salisbury (ca. 1120-1180): “Bernard of Chartres and his students worked hard to reconcile Aristotle and Plato. But in my judgment they arrived late, so they strove in vain to reconcile two dead men, who could have reconciled as long as they were alive, but disagreed.” John of Salisbury, *Metalogicon*, bk. 2, c. 17, 875d22-25.

4. Cf.: “In the second place it is clear what those professors mean who say that there are three sorts of universals, namely, before the individual thing, as an idea, in the thing, as a form communicated to many things, and after the thing, as the species or sign of the former.” John Wyclif, *Tractatus de Universalibus*, c. 2, p. 69. Cf. also: “To these two kinds of universals [Plato's and Aristotle's], a third is added, namely, the species in the understanding abstracted from the things is called universal, because it is related to many things, not because it is predicated of many, but because it is similar to many. … And perhaps this is whence the distinction originated that there are three kinds of universals: before the thing, in the thing, and after the thing. For a universal in the first way is before the thing, because it causes things. In the second way it is in the thing, because it is the same essence as the things. In the third way it is after the thing, because it is a species abstracted from the things and caused by them.” Giles of Rome, *In Primum Librum Sententiarum*, 1SN, d. 19, pars 2, q. 1. *Utrum in divinis sit totum universale?*. Concerning alleged “ontological extremities” in mediaeval philosophy see J. A. Trentman's *Introduction* to his edition of Vincent Ferrer's *Tractatus de Suppositionibus*, esp. pp. 20-30.

5. Notable exceptions would be Ockham, and his followers, such as Peter of Ailly, John Gerson, and Gabriel Biel. See Ockham, *Ordinatio* I, d. 35, q. 5, and Biel, *Collectorium* I, d. 35, q. 5. These authors argue that only singular creatures have ideas in the divine mind (which they identify with the singular creatures themselves as they are eternally pre-cognized by God), but neither their species, nor their genera do. To be sure, since created intellects do form universal concepts of singulars, and God does have cognition of those concepts in each singular created mind from eternity, in a roundabout way these authors still concede that there are universals in the divine mind. However, Ockham also claims that in

the divine mind these universals do not function as universal exemplars, as they do in the minds of created agents. But regardless of such details, the point is that even such hardheaded nominalists would not directly go against the authority of St. Augustine on this issue, for which see the section on divine ideas below.

6. Porphyry, *Isagoge*, in Spade 1994 (henceforth, *Five Texts*), p. 1.

7. In fact, by the 12th century the irresistible challenge posed by Porphyry's questions yielded a proliferation of answers that John of Salisbury found pedagogically completely unjustifiable, complaining in his *Metalogicon* that his contemporaries' endless discussions of universals in connection with what was supposed to be an introductory logic text placed “unbearable burden on the tender shoulders of their students” (*onera importabilia teneris auditorum humeris imponunt*). *op. cit.*, bk. 2, c. 19, 877a.

8. As Paul Spade has pointed out in his careful analysis of Boethius' argument, this characterization of what a universal is derives from Porphyry's commentary on Aristotle's *Categories.* See, Spade 1996b.

9. Although Boethius does not explicitly formulate his argument in terms of the distinctness and identity of the acts of being of the entities in question, in the conclusion of his argument, he quite explicitly alludes to the Aristotelian principle of the convertibility of unity and being. See Spade 1996b, p. 22 (12). In any case, this reformulation of Boethius' argument is just my attempt at clarifying what Boethius' may have meant by the requirement of metaphysical “constitutiveness” that accounts for the key motive in the argument which Paul Spade very aptly called the “contagiousness” of the plurality of the particulars.

10. To be sure, Boethius does not explicitly talk about a *collection* here, but this suggestion is certainly very similar to those later collection-theories which Abelard vehemently (and quite effectively) criticized. See *Five Texts*, pp. 35-37. In any case, in Boethius' argument nothing depends on whether the several items demanding a genus are grouped together into a collection, a quasi-entity with its own less-than-numerical quasi-unity. The point is that according to the assumption of this part of the argument, the term ‘genus’ has to stand for a number of distinct entities, no matter whether they are taken to form a collection or not.

11. This summary provides the overall structure of Boethius' argument. In the reconstruction above I did not follow the order of Boethius' actual presentation; I merely summarized what I take to be the gist of Boethius' reasoning. For an intriguing and thoroughgoing discussion of the interpretational possibilities as to the actual “fine-structure” of Boethius' argumentation, see again Spade 1996b.

12. *Five Texts*, p. 23 (21).

13. The same solution recurs, in ever more refined forms, e.g., in Abelard (*Five Texts*, p. 48), John of Salisbury (*Metalogicon*, bk. 2, c. 20, 877c7-878a9), and Aquinas (ST1, q. 85, a. 1, ad 1-um.).

14. To be sure, I may still be mistaken about *what* a man *is*. But that, again, would be a case of forming a judgment, as opposed to simply conceiving of man without any judgment whatsoever. The point is that by an act of simple apprehension I either do conceive of a certain (kind of) thing, or I don't. If I do, then in this act there cannot be falsity unless I make a judgment about the thing conceived; if I don't, then I literally have no idea of the thing, so I will certainly not make a judgment about it, let alone a false one.

15. Note that Berkeley's famous criticism of the Lockean conception of abstraction does not apply here, for abstraction in this sense, as selective intellectual attention, was admitted even by George Berkeley, in a significant insertion in the second edition of the *Introduction* to his *Principles*. See George Berkeley: *A Treatise Concerning the Principles of Human Knowledge*, p. 16.

16. *Five Texts*, p. 25.

17. The tradition goes back to Philo of Alexandria, and the Alexandrian school of Ammonius Saccas. See Spade 1985, p. 67. An excellent, detailed discussion of Greek and Arab Neo-Platonism is provided in Libera 1996. Interestingly, Aquinas, following Averroes, attributes this theory to Aristotle. Cf. 1SN, d. 36, q. 2, a. 1, ad 1-um. Domingo Soto, besides referring to the *locus classicus* from Augustine quoted below, indicates that he also found the same doctrine in the "through and through Platonic" (*ubique Platonicus*) Seneca. Cf. Soto, D., *In Porphyrii Isagogen, Aristotelis Categorias, librosque de Demonstratione, Commentaria*, p. 30 I. For Seneca, see, e.g., *Ad Lucilium Epistulae Morales*, lxx.7; lxv. 4-7. Seneca is also quoted by Ockham and Biel in the places referred to in n. 5 above.

18. *Five Texts*, p. 25.

19. *On Eighty-Three Different Questions*, q. 46, 2, translated by P. V. Spade (in Spade 1985, p. 383) from Augustine, *De diversis quaestionibus octoginta tribus*.

20. *Ibid*.

21. Quite significantly, Aquinas quotes Augustine as his authority for this position: "Augustine says (De Trin. iv, 6,7): 'God is truly and absolutely simple.'" ST1, q. 3, a. 7, sc. (See the whole question for Aquinas' detailed arguments for God's simplicity.)

22. ST1, q. 15, a. 2.

23. Cf.: Henry of Ghent, *Summa Quaestionum Ordinariarum*, 2, a. 65, q. 5; John Duns Scotus, *Op. Oxon*. lb. 1, d. 35, q. *unica*. Thomas of Sutton, *Quodlibeta*, IV, q. 5. For Aquinas' detailed discussion of the issue one should check 1SN, d. 36, q. 2, aa. 1-3.

24. *On the Free Choice of the Will*, II, 8; cf. *Phaedo*, 73c-75c, in Plato, *Collected Dialogues*.

25. *In De Anima*, bk. 3, lc. 10.

26. Note that this premise merely assumes the abstraction of the concept of some sort of unity, found, for example, in the experience of single bodies (which really *is* common experience), and not the formation of the concept of absolute unity, which would require (at least) the further steps indicated below. Of course, the premise also presumes the Aristotelian conception that the intellective soul has an active intellect, the active faculty enabling it to perform abstraction.

27. See Klima 2000b.

28. ST1, q. 84, a. 5.

29. An excellent collection of relevant texts can be found in Bonaventure, *et al*., *De Humanae Cognitionis Ratione: anecdota quaedam Seraphici Doctoris Sancti Bonaventurae et nunnulorum eius discipulorum*.

30. For more on this issue see Pasnau 1999b.

31. As John of Salisbury writes: "…everybody follows Aristotle" (…*omnes Aristotelem profitentur*). *Metalogicon*, bk. 2, c. 19, 877a18.

32. *Five Texts*, p. 41 (88).

33. Cf. Spade 1985, c. 40, where P. V. Spade carefully identifies Abelard's opponents on the basis of John of Salisbury's encyclopedic account of the current views on universals of his time.

34. No wonder that in modern philosophies of language, mostly inspired by the "collection-theorist" view of quantification theory, we have the persistent problem of providing a principled distinction between essential and non-essential predicates.

35. The term *status* (the plural form of which is also *status*, pronounced with a long *u*) designates just a state of a thing, the way the thing is. It is this simple, intuitive idea that gains some further, technical significance in the context of Abelard's theory.

36. Cf. Aristotle, *Physics*, 2, c. 3, 195 a13-14. Note that the *Physics* was not yet available in Abelard's time. Abelard's own examples include being flogged for not appearing in court, being hanged for stealing, dying because of not eating, and being damned for not acting rightly. In any case, Abelard's point clearly is that he takes the causal relation to hold between the *significata* of whole propositions, regardless of the particular content of these propositions, or the particular kind of causality involved.

37. This will immediately raise the problem whether the *status* of created things are there before their

creation, and if not (since nothing other than God can be coeternal with God), then whether God's providence of created things before their creation was empty. Abelard explicitly raises and answers this problem. Cf. *Five Texts*, pp. 49-50 (135)-(140).

38. *Five Texts*, p. 47 (123). Indeed, according to the immediately following paragraph (124), the *status* has a "greater force" in determining the community of universal names; so it may even be *primarily* signified by a common term.

39. *Five Texts*, p. 46 (116).

40. In fact, I think this may be an early anticipation of the distinction that appears in Aquinas, who distinguishes between that *from which* a name is imposed, and that *on which* the name is imposed, what is *intended* to be signified. For more on this distinction, see Klima 1996a.

41. For a more detailed discussion of the philosophical issues raised by Abelard's theory, see Tweedale 1982, and Spade 1985, c. 40.

42. Avicenna: *Metaphysica* V, 1, at II, p. 228 lines 31-36; 1508 ed., fol. 86va; tr. in Spade 1985, c. 21, p. 461.

43. *De ente et essentia*, c. 2 (in *Opera Omnia*)

44. In this connection the analogy perfectly applies to what Aristotle and Aquinas had to say about monstrous births, and what we know about genetic errors.

45. Cf. Klima 1993a.

46. "Human nature has in the intellect existence abstracted from all individuals, and thus it is related uniformly to all individuals that exist outside the soul, as it is equally similar to all of them, and it leads to knowledge of all insofar as they are men. Since the nature in the intellect has this relation to each individual, the intellect invents the notion of species and attributes it to itself. Hence, the Commentator, in *De Anima* I, com. 8, says, "The intellect is what makes universality in things," and Avicenna says the same in his *Metaphysicae* V, cap. 2. Although this nature understood in the intellect has the notion of a universal in relation to things outside the soul (because it is one likeness of them all), as the nature has existence in this intellect or in that one, it is a certain particular understood species." Aquinas, *De ente et essentia*, c. 3 (in *Opera Omnia*). Cf. Suarez, F., *Disputaciones Metafisicas*, pp. 360-361. For a somewhat different interpretation of the same distinction, however, cf. also Cajetan, *Commentary on Being and Essence*, pp. 67-71, 121-124.

47. Cf. Klima 1993b and Schmidt 1966.

48. For a more detailed, systematic discussion of the issue of different "degrees of being" and different "degrees of unity" this conception entails see Klima 1996a and 2000b.

49. See more on Olivi in Pasnau 1999a. For more discussion of the issue of intermediaries in cognition in medieval philosophy, especially in Aquinas, its relation to skepticism, and whether it should be construed in terms of the modern "direct realist" vs. "representationalist" distinction, see Klima 1996b. (See also *Appendix A* of Pasnau 1997).

50. Cf. For an excellent, brief "textbook-treatment" of, and relevant excerpts from, the 1277 condemnations see "The Condemnation of 1277", in A. Hyman and J. J. Walsh, (eds.), *Philosophy of the Middle Ages*, which also provides further scholarly references. For a thoroughgoing discussion, see Hissette 1977.

51. For Henry's view, as opposed and criticized by the Thomist theologian Thomas of Sutton, see Klima 2000a. For the same, as criticized by Duns Scotus, see *Five Texts*, pp. 69-71. For in-depth contemporary discussions of the problem of individuation in the Middle Ages, see Gracia 1994. For a comprehensive account of the early history of the problem, see Gracia 1984.

52. Cf. Suarez, F., *On the Various Kinds of Distinctions*.

53. Cf. Callus 1967.

54. Ockham, W. *Summa Logicae*, part 1, c. 51, p. 169.

55. *Ibid*., p. 171, where Ockham explicitly claims that this is the root (*radix*) of the errors of the moderns.

56. I argue for this claim in detail in Klima 1999.

57. For a recent summary of the development of Ockham's views on this matter see Pasnau 1997, pp. 277-289, esp. p. 278, n. 47, where the author provides further references to the existing secondary literature. A particularly illuminating account of Ockham's early *fictum* theory is provided by Read 1977.

58. To be sure, this conception of indifference of representation based on essential similarity of the represented things raises a number of further questions which seriously challenge the successfulness of Ockham's semantic program on the level of how the fundamental semantic relation between concepts and things is established. A detailed discussion of this issue can be found in Klima 1997 [Klima 1997]. Cf. also Adams 1987, I, c.3, pp. 121-133.

59. In medieval logic (regardless of many disagreements over the details between individual authors), *personal supposition* (when a term is used to refer in a proposition to something of which it can truly be

predicated with the mediation of the copula of the proposition in question) was commonly distinguished from *simple supposition* (when the term is used to refer to its *immediate significate*), and *material supposition* (when the term is used to refer to itself or other tokens of its type). For a brief, summary account of the medieval theories of the properties of terms, see Spade 1982. For *much* more, see Spade 1996a.

60. Again, this need not necessarily be regarded as a flaw of this theory. After all, in our age of satellite uplinks and computer networks we should not find the idea of *the same* information content (which is nothing but the *objective concept* in the scholastic jargon) being realized in several, physically radically different media. (Indeed, *Napster* would not be in trouble, if the recording companies did not think that the music downloaded is the same that they had recorded.)

61. For detailed, systematic comparisons of the different semantic principles of the two *viae*, see Klima 1993b and 1999.

62. Cf. Aristotle, *Physics*, III, 3, 202a15-202b29; *Metaphysics*, XI, 9, 1066a17-34.

63. An excellent survey of the medieval theories of relations is provided by Henninger 1989.

64. Soto, D., *In Porphyrii Isagogen, Aristotelis Categorias, librosque de Demonstratione, Commentaria*, p. 28H.

65. *Ibid*.

66. For an excellent historical survey of these developments see Ashworth 1974.

67. Documents of the typical humanistic reaction are provided with Rita Guerlac's excellent introduction in Vives, J. L., *Against the Pseudodialecticians*.

The Language of Thought Hypothesis

The Language of Thought Hypothesis (LOTH) postulates that thought and thinking take place in a mental language. This language consists of a system of representations that is physically realized in the brain of thinkers and has a combinatorial syntax (and semantics) such that operations on representations are causally sensitive only to the syntactic properties of representations. According to LOTH, thought is, roughly, the tokening of a representation that has a syntactic (constituent) structure with an appropriate semantics. Thinking thus consists in syntactic operations defined over such representations. Most of the arguments for LOTH derive their strength from their ability to explain certain empirical phenomena like productivity and systematicity of thought and thinking.

What is the Language of Thought Hypothesis?

LOTH is an empirical thesis about the nature of thought and thinking. According to LOTH, thought and thinking are done in a mental language, i.e. in a symbolic system physically realized in the brain of the relevant organisms. In formulating LOTH, philosophers have in mind primarily the variety of thoughts known as 'propositional attitudes'. Propositional attitudes are the thoughts described by such sentence forms as '*S* believes that *P*', '*S* hopes that *P*', '*S* desires that *P*', etc., where '*S*' refers to the subject of the attitude, '*P*' is any sentence, and 'that *P*' refers to the proposition that is the object of the attitude. If we let '*A*' stand for such attitude verbs as 'believe', 'desire', 'hope', 'intend', 'think', etc., then the propositional attitude statements all have the form: *S A*s that *P*.

LOTH can now be formulated more exactly as a hypothesis about the nature of propositional attitudes. It can be characterized as the conjunction of the following three theses (A), (B) and (C):

(A) Representational Theory of Mind (RTM): (cf. Field 1978: 37, Fodor 1987: 17)

> (1) Representational Theory of Thought: For each propositional attitude *A*, there is a unique and distinct (i.e. dedicated)[1] psychological relation *R*, and for all propositions *P* and subjects *S*, *S A*s that *P* if and only if there is a mental representation #*P*# such that
>
>> (a) *S* bears *R* to #*P*#, and
>> (b) #*P*# means that *P*.
>
> (2) Representational Theory of Thinking: Mental processes, thinking in particular, consists of causal sequences of tokenings of mental representations.

(B) Mental representations, which, as per (A1), constitute the direct "objects" of propositional attitudes, belong to a representational or symbolic *system* which is such that (cf. Fodor and Pylyshyn 1988:12-3)

> (1) representations of the system have a combinatorial syntax and semantics: structurally complex (molecular) representations are systematically built up out of structurally simple (atomic) constituents, and the semantic content of a molecular representation is a function of the semantic content of its atomic constituents together with its syntactic/formal structure, *and*
>
> (2) the operations on representations (constituting, as per (A2), the domain of mental processes, thinking) are causally sensitive to the syntactic/formal structure of representations defined by this combinatorial syntax.

(C) Functionalist Materialism. Mental representations so characterized are, at some suitable level, functionally characterizable entities that are realized by the physical properties of the subject having

propositional attitudes (if the subject is an organism, then the realizing properties are presumably the neurophysiological properties in the brain or the central nervous system of the organism).

The relation *R* in (A1), when RTM is combined with (B), is meant to be understood as a *computational/functional* relation. The idea is that each attitude is identified with a characteristic computational/functional role played by the mental sentence that is the direct "object" of that kind of attitude. (Scare quotes are necessary because it is more appropriate to reserve ‘object’ for a proposition as we have done above, but as long as we keep this in mind, it is harmless to use it in this way for LOT sentences.) For instance, what makes a certain mental sentence an (occurrent) belief might be that it is characteristically the output of perceptual output systems and input to an inferential system that interacts decision-theoretically with desires to produce further sentences or actions. Or equivalently, we may think of belief sentences as those that are accessible only to certain sorts of computational operations appropriate for beliefs, but not to others. Similarly, desire-sentences (and sentences for other attitudes) may be characterized by a different set of operations that define a characteristic computational role for them. In the literature it is customary to use the metaphor of a "belief-box" (cf. Schiffer 1981) as a blanket term to cover whatever specific computational role belief sentences turn out to have in the mental economy of their possessors. (Similarly for "desire-box", etc.)

The Language of Thought Hypothesis is so-called because of (B): token mental representations are like sentences in a language in that they have a syntactically and semantically regimented constituent structure. Put differently, mental representations that are the direct "objects" of attitudes are structurally complex symbols whose complexity lends itself to a syntactic and semantic analysis. This is also why the LOT is sometimes called *Mentalese*.

It is (B2) that makes LOTH a species of the so-called Computational Theory of Mind (CTM). This is why LOTH is sometimes called the Computational/Representational Theory of Mind or Thought (CRTM/CRTT) (cf. Rey 1991, 1997). Indeed, LOTH seems to be the most natural product when RTM is combined with a view that would treat mental processes or thinking as computational when computation is understood traditionally or *classically* (this is a recent term emphasizing the contrast with connectionist processing, which we will discuss later).

When someone believes that *P*, there is a trivial sense in which the immediate "object" of her belief, what she believes, can be said to be a complex symbol, according to LOTH, a sentence in her LOT physically realized in the neurophysiology of her brain, that has both syntactic structure and a semantic content, namely the proposition that *P*. So, contrary to the orthodox view that takes the belief relation as a dyadic relation between an agent and a proposition, LOTH takes it to be a triadic relation among an agent, a Mentalese sentence, and a proposition. The Mentalese sentence can then be said to have the proposition as its semantic/intentional content. It is only in this (perhaps indirect) sense can it be said that what is believed is a proposition, and thus the *object* of the attitude in more common philosophical parlance.

This triadic view seems to have an advantage over the orthodox dyadic view in that it is a puzzle in the dyadic view how what are thought to be purely physical organisms can stand in direct relation to abstract objects like propositions in such a way as to influence their causal powers. According to **folk psychology**,

it is because those states have the propositional content they do that they have the causal powers they do. LOTH makes this relatively non-mysterious by introducing a physical intermediary that is capable of having the relevant causal powers in virtue of its syntactic structure that encodes its semantic content. Another advantage of this is that the thought processes can be causally guided by the syntactic forms of the sentences in a way that respect their semantic contents. This is the virtue of (B) to which we'll come back below. Mainly because of these features, LOTH is said to scientifically vindicate folk psychology if it turns out to be true.

Status of LOTH

LOTH has primarily been advanced as an *empirical* thesis (although some have argued for the truth of LOTH on a priori or conceptual grounds, given the natural conceptual contours of folk psychology -- see Davies 1989, 1991; Lycan 1993; Rey 1995). It is not meant to be taken as an analysis of what the folk *mean* (or, for that matter, what the scientists ought to mean) when they talk about various propositional attitudes and their role in thinking. In this regard, LOT theorists typically view themselves as engaged in some sort of a proto-science, or at least in some empirical research program continuous with scientific psychology or more generally with empirical inquiry. Indeed, as we will see in more detail below, when Jerry Fodor first explicitly articulated and elaborated LOTH in some considerable detail in his (1975), he basically defended it on the ground that it was assumed by our best scientific theories or models in cognitive psychology and psycholinguistics. This empirical status accorded to LOTH should be kept firmly in mind when assessing its plausibility and especially its prospects in the light of new evidence and developments in scientific psychology.

When viewed this way, LOTH is not, strictly speaking, committed to preserving the folk taxonomy of the mental states in any very exact way. Notions like belief, desire, hope, fear, etc. are folk notions and, as such, it may not be utterly plausible to expect (eliminativist arguments aside) that a scientific psychology will preserve the exact contours of these concepts. On the contrary, there is every reason to believe that scientific counterparts of these notions will carve the mental space somewhat differently. For instance, it has been noted that the folk notion of belief harbors many distinctions. It is noted for example that it has both a dispositional and an occurrent sense. In the occurrent sense, it seems to mean something like consciously entertaining and accepting a thought (proposition) as true. There is quite a bit of literature and controversy on the dispositional sense.[2] Beliefs are also capable of being explicitly stored in long term memory as opposed to being merely dispositional or tacit. Compare, for instance: I believe that there was a big surprise party for my 24th birthday vs. I have always believed that lions don't eat their food with forks and knives, or that 13652/4=3413, even though until now these latter two thoughts had never occurred to me. There is furthermore the issue of degree of belief: while I may believe that George will come to dinner with his new girlfriend even though I wouldn't bet on it, you, thinking that you know him better than I do, may nevertheless go to the wall for it. It is unlikely that there will be one single construct of scientific psychology that will exactly correspond to the folk notion of belief in all these ways.

For LOTH to vindicate folk psychology it is sufficient that a scientific psychology with a LOT architecture come up with scientifically grounded psychological states that are recognizably like the

propositional attitudes of folk psychology, and that play more or less similar roles in psychological explanations.[3]

Scope of LOTH

LOTH is an hypothesis about the nature of thought and thinking with propositional content. As such, it may or may not be applicable to other aspects of mental life. Officially, it is silent about the nature of some mental phenomena such as experience, **qualia**,[4] sensory processes, mental images, visual and auditory imagination, sensory memory, perceptual pattern-recognition capacities, dreaming, hallucinating, etc. To be sure, many LOT theorists hold views about these aspects of mental life that make it seem that they are also to be explained by something similar to LOTH.[5]

For instance, Fodor seems to think that many modular input systems (Fodor 1983) have their own LOT to the extent to which they can be explained in representational and computational terms. Indeed, many contemporary psychological models treat perceptual input systems in just these terms.[6] There is indeed some evidence that this kind of treatment is appropriate for many perceptual processes. But it is to be kept in mind that a system may employ representations and be computational without necessarily satisfying any or both of the clauses in (B) above in any full-fledged way. Just think of finite automata theory where there are plenty of examples of a computational process defined over states or symbols which lack full-blown syntactic and/or semantic structural complexity. Whether sensory or perceptual processes are to be treated within the framework of full-blown LOTH is again an open empirical question. It may well be that the answer to this question is affirmative. If so, there may be more than one LOT realized in different subsystems or mechanisms in the mind/brain. So LOTH is not committed to there being a single representational system realized in the brain, nor is it committed to the claim that all mental representations are complex or language-like, nor would it be falsified if it turns out that most aspects of mental life other than the ones involving propositional attitudes don't require a LOT.

Similarly, there is strong evidence that the mind also exploits an image-like representational medium for certain kinds of mental tasks.[7] LOTH is non-committal about the existence of an image-like representational system for many mental tasks other than the ones involving propositional attitudes. But it *is* committed to the claim that propositional thought and thinking cannot be successfully accounted for in its entirety in purely imagistic terms. It claims that a combinatorial sentential syntax is necessary for propositional attitudes and a purely imagistic medium is not an adequate medium to capture that.[8]

There are in fact some interesting and difficult issues surrounding these claims. The adequacy of an imagistic system seems to turn on the nature of syntax at the *sentential* level. For instance, Fodor, in Chapter 4 of his (1975) book, allows that many lexical items in one's LOT may be image-like; he introduces the notion of a *mental image/picture under description* to avoid some obvious inadequacies of pictures (e.g., what makes a picture a picture of a fat woman rather than a pregnant one, or vice versa, etc.). This is an attempt to combine discursive and imagistic representational elements at the *lexical* level. There may even be a well defined sense in which pictures can be combined to produce structurally complex pictures (as in British Empiricism: image-like simple ideas are combined to produce complex

ideas, e.g., the idea of a unicorn) But what is absolutely essential for LOTH, and what Fodor insists on, is the claim that there is no adequate way in which a purely image-like system can capture what is involved in making judgments, i.e., in judging *propositions* to be true. This seems to require a discursive syntactic approach at the sentential level. The general problem here is the inadequacy of pictures or image-like representations to express propositions. I can judge that the blue box is on top of the red one without judging that the red box is under the blue one. I can judge that Mary kisses John without judging that John kisses Mary, and so on for indefinitely many such cases, concrete as well as abstract. It is hard to see how images or pictures can do that without using any syntactic structure or discursive elements, to say nothing of judging, e.g., conditionals, disjunctive or negative propositions, quantifications, negative existentials, etc.[9]

Moreover, there are difficulties with imagistic representations arising from demands on *processing* representations . As we will see below, (B2) turns out to provide the foundations for one of the most important arguments for LOTH: it makes it possible to mechanize thinking understood as a semantically coherent thought process, which, as per (A2), consists of a causal sequence of tokenings of mental representations. It is not clear, however, how an equivalent of (B2) could be provided for images or pictures in order to accommodate operations defined over them, even if something like an equivalent of (B1) could be given. On the other hand, there are truly promising attempts to *integrate* discursive symbolic theorem-proving with reasoning with image-like symbols. They achieve impressive efficiency in theorem-proving or in any deductive process defined over the expressions of such an integrated system. Such attempts, if they prove to be generalizable to psychological theorizing, are by no means threats to LOTH; on the contrary, such systems have every features to make them a species of a LOT system: they satisfy (B).[10]

Nativism and LOTH

In the book (1975) in which Fodor introduced the LOTH, he also argued that all concepts are innate. As a result, the connection between LOTH and an implausibly strong version of conceptual nativism looked very much internal. This historical coincidence has led some people to think that LOTH is essentially committed to a very strong version of nativism, so strong in fact that it seems to make a *reductio* of itself (see, for instance, P.S. Churchland 1986, Putnam 1988, Clark 1994). The gist of his argument was that since learning concepts is a form of hypothesis formation and confirmation, it requires a system of mental representations in which formation and confirmation of hypotheses are to be carried out, but then there is a non-trivial sense in which one already has (albeit potentially) the resources to express the extension of the concepts to be learned.

However, it should be emphasized that LOTH is not committed to such a strong version of nativism, especially about concepts. It is certainly plausible to assume that LOTH will turn out to have some empirically (as well as theoretically/a priori) motivated nativist commitments about the structural organization and dynamic management of the entire representational system. But this much is to be expected especially in the light of recent empirical findings and trends. This, however, does not constitutes a *reductio*. It is an open empirical question how much nativism is true about concepts, and

LOTH should be so taken as to be capable of accommodating whatever turns out to be true in this matter. LOTH, therefore, when properly conceived, is independent of any specific proposal about conceptual nativism.[11]

Naturalism and LOTH

One of the most attractive features of LOTH is that it is a central component of an ongoing research program in philosophy of psychology to naturalize the mind, to give a theoretical framework in which the mind could naturally be seen as part of the physical world without postulating irreducibly psychic entities, events, processes or properties. Fodor, the most ardent defender of LOTH, once identified the major mysteries in philosophy of mind thus:

> How could anything material have conscious states? How could anything material have semantical properties? How could anything material be rational? (where this means something like: how could the state transitions of a physical system preserve semantical properties?). (1991: 285, Reply to Devitt)

LOTH is a full-blown attempt to give a naturalist answer to the third question, an attempt to solve at least part of the problem underlying the second one, and is almost completely silent about the first.[12]

According to RTM, propositional attitudes are relations to meaningful mental representations whose tokenings constitute the domain of thinking. This much can, in principle, be granted by an intentional realist who would nevertheless reject LOTH. Indeed, there are plenty of theorists who accept RTM in some suitable form (and also happily accept (C) in many cases) but reject LOTH either by explicitly rejecting (B) or simply by remaining neutral about it. Among some of the prominent people who choose the former option are Searle (1984, 1990, 1992), Stalnaker (1984), Lewis (1972), Barwise and Perry (1983).[13] Some who opt for the latter include Loar (1982a, 1982b), Dretske (1981); Armstrong (1980), and many contemporary functionalists.[14]

But RTM per se doesn't so much propose a naturalistic solution to intentionality and mechanization of thinking as simply assert a framework to emphasize intentional realism and, perhaps, with (C), a declaration of a commitment to naturalism or physicalism at best. How, then, is the addition of (B) supposed to help? Let us first try to see in a bit more detail what the problem is supposed to be in the first place to which (B) is proposed as a solution. So let us start by reflecting on thinking and see what it is about thinking that makes it a mystery in Fodor's list. This will give rise to one of the most powerful (albeit still nondemonstrative) arguments for LOTH.

The Problem of Thinking

RTM's second clause (A2), in effect, says that thinking is at least the tokenings of states that are (a) intentional (i.e. have representational/propositional content) and (b) causally connected. But, surely,

thinking is more. There could be a causally connected series of intentional states that makes no sense at all. Thinking, therefore, is causally proceeding from states to states that would make semantic sense: the transitions among states must preserve some of their semantic properties to count as thinking. In the ideal case, this property would be the truth value of the states. But in most cases, any interesting intentional property like warrantedness, degree of confirmation, semantic coherence given a certain practical context like satisfaction of goals in a specific context, etc. would do. In general, it is hard to spell out what this requirement of "making sense" comes to. The intuitive idea, however, should be clear. Thinking is not proceeding from thoughts to thoughts in arbitrary fashion: thoughts that are causally connected are in some fashion semantically connected too. If this were not so, there would be little point and gain in thinking. Thinking couldn't serve any useful purpose. Call this general phenomenon, then, the *semantic coherence* of causally connected thought processes. LOTH is offered as a solution to this puzzle: how is thinking, conceived this way, physically possible? This is the problem of thinking, thus the problem of mechanization of rationality in Fodor's version. How does LOTH propose to solve this problem and bring us one big step closer to the naturalization of the mind?

Syntactic Engine Driving a Semantic Engine: Computation

The two most important achievements of 20th century that are at the foundations of LOTH as well as most of modern Artificial Intelligence (AI) research and the so-called information processing approaches to cognition (practically almost all of contemporary cognitive psychology) are (i) the developments in modern symbolic (formal) logic, and (ii) **Alan Turing**'s idea of a Turing Machine and Turing computability. It is putting these two ideas together that gives LOTH its enormous explanatory power within a naturalistic framework. Modern logic showed that most of deductive reasoning can be formalized, i.e. most semantic relations among symbols can be entirely captured by the symbols' formal/syntactic properties and the relations among them. And Turing showed, roughly, that if a process has a formally specifiable character then it can be mechanized. So we can appreciate the implications of (i) and (ii) for the philosophy of psychology in this way: if thinking consists in processing representations physically realized in the brain (in the way the internal data structures are realized in a computer) and these representations form a formal system, i.e. a language with its proper combinatorial syntax (and semantics) and a set of derivations rules formally defined over the syntactic features of those representations (allowing for specific but extremely powerful programs to be written in terms of them), then the problem of thinking, as I described it above, can in principle be solved in completely naturalistic terms, thus the mystery surrounding how a physical device can ever have semantically coherent state transitions (processes) can be removed. Thus, given the commitment to naturalism, the hypothesis that the brain is a kind of computer trafficking in representations in virtue of their syntactic properties is the basic idea of LOTH (and the AI vision of cognition).

Computers are environments in which symbols are manipulated in virtue of their formal features, but what is thus preserved are their semantic properties, hence the semantic coherence of symbolic processes. Slightly paraphrasing Haugeland (cf. 1985: 106), who puts the same point nicely in the form of a motto:

> **THE FORMALIST MOTTO**:
> If you take care of the syntax of a representational system, its semantics will take care of

itself.

This is in virtue of the mimicry or mirroring relation between the semantic and formal properties of symbols. As Dennett once put it in describing LOTH, we can view the thinking brain as a syntactically driven engine preserving semantic properties of its processes, i.e. driving a semantic engine. What is so nice about this picture is that if LOTH is true we have a naturalistically adequate causal treatment of *thinking* that respect the semantic properties of the *thoughts* involved: it is in virtue of the physically coded syntactic/formal features that thoughts cause each other while the coherence of their semantic properties is preserved precisely in virtue of this.

Whether or not LOTH actually turns out to be empirically true in the details or in its entire vision of rational thinking, this picture of a syntactic engine driving a semantic one can at least be taken to be an important *philosophical* demonstration of how Descartes' challenge can be met (cf. Rey 1997: chp.8). Descartes claimed that rationality in the sense of having the power "to act in all the contingencies of life in the way in which our reason makes us act" cannot possibly be possessed by a purely physical device: "The rational soul ... could not be in any way extracted from the power of matter ... but must ... be expressly created" (1637/1970: 117-18). Descartes was completely puzzled by just this rational character and semantic coherence of thought processes so much so that he failed to even imagine a possible mechanistic explication of it. He thus was forced to appeal to Divine creation. But we can now see/imagine at least a possible mechanistic/naturalistic scenario.[15]

Intentionality and LOTH

But where do the semantic properties of the mental representations come from in the first place? How can they mean anything? This is Brentano's challenge to a naturalist. Brentano's bafflement was with the **intentionality** of the human mind, its apparently mysterious power to represent things, events, properties in the world. He thought that nothing physical can have this property of intentionality: "The reference to something as an object is a distinguishing characteristic of all mental phenomena. No physical phenomenon exhibits anything similar" (Brentano 1874/1973: 97). This problem of intentionality is the second problem or mystery in Fodor's list that I quoted above. I said that LOTH officially offers only a partial solution to it and perhaps proposes a framework within which the remainder of the solution can be couched and elaborated in a naturalistically acceptable way.

As characterized at the beginning, RTM contains a clause (A1b) that says that the immediate object of a propositional attitude that *P* is a mental representation #*P*# that *means* that *P*. Again, (B1) attributes a compositional semantics to the syntactically complex symbols belonging to one's LOT that are, as per (C), physically realized in the brain of a thinking organism. According to LOTH, the semantic content of propositional attitudes is inherited from the semantic content of the mental symbols. So Brentano's questions for a LOT theorist becomes: how do the symbols in one's LOT get their meanings in the first place? There are two levels or stages at which this question can be raised and answered:

(1) At the level of *atomic* (simple) symbols: how do the atomic symbols represent what

they do?

(2) At the level of *molecular* (phrasal complexes or sentences) symbols: how do molecular symbols represent what they do?

There have been at least two major lines LOT theorists have taken regarding these questions. The one that is least committal might perhaps be usefully described as the official position regarding LOTH's treatment of intentionality. Most LOT theorists seem to have taken this line. The official line doesn't propose any theory about the first stage, but simply assumes that the first question can be answered in a naturalistically acceptable way. In other words, officially LOTH simply assumes that the atomic symbols/expressions in one's LOT have whatever meanings they have.[16]

But, the official line continues, LOTH has a lot to say about the second stage, the stage where the semantic contents are computed or assigned to complex (molecular) symbols on the basis of their combinatorial syntax or grammar together with whatever meanings atomic symbols are assumed to have in the first stage. This procedure is familiar from a Tarski-style[17] definition of truth conditions of *sentences*. The truth-value of complex sentences in propositional logic are completely determined by the truth-values of the atomic sentences they contain together with the rules fixed by the truth-tables of the connectives occurring in the complex sentences. Example: '*P* and *Q*' is true just in case both '*P*' and '*Q*' are true, but false otherwise. This process is similar but more complex in first-order languages, and even more so for natural languages -- in fact, we don't have a completely working compositional semantics for the latter at the moment. So, *if* we have a semantic interpretation of atomic symbols (*if* we have symbols whose reference and extension are fixed at the first stage by whatever naturalistic mechanism turns out to govern it), *then* the combinatorial syntax will take over and effectively determine the semantic interpretation (truth-conditions) of the complex sentences they are constituents of. So officially LOTH would only contribute to a complete naturalization project if there is a naturalistic story at the atomic level.

Early Fodor (1975, 1978, 1978a, 1980), for instance, envisaged a science of psychology which, among other things, would reasonably set for itself the goal of discovering the combinatorial syntactic principles of LOT and the computational rules governing its operations, without worrying much about semantic matters, especially about how to fix the semantics of atomic symbols (he probably thought that this was not a job for LOTH). Similarly, Field (1978) is very explicit about the combinatorial rules for assigning truth-conditions to the sentences of the internal code. In fact, Field's major argument for LOTH is that, given a naturalistic causal theory of reference for atomic symbols, about which he is optimistic (Field 1972), it is the only naturalistic theory that has a chance of solving Brentano's puzzle. For the moment, this is not much more than a hope, but, according to the LOT theorist, it is a well-founded hope based on a number of theoretical and empirical assumptions and data. Furthermore, it is a framework defining a naturalistic research program in which there have been promising successes.[18]

As I said, this official and, in a way, least committal line has been overall the more standard way of conceiving LOTH's role in the project of naturalizing intentionality. But some have gone beyond it and explored the ways in which the resources of LOTH can be exploited even in answering the first question

(1) about the semantics of atomic symbols.

Now, there is a weak version of an answer to (1) on the part of LOTH and a strong version. On the weak version, LOTH may be untendentiously viewed as inevitably providing *some* of the resources in giving the ultimate naturalistic theory in naturalizing the meaning of atomic symbols. The basic idea is that whatever the ultimate naturalistic theory turns out to be true about atomic expressions, computation as conceived by LOTH will be part of it. For instance, it may be that, as with nomic covariation theories of meaning (Fodor 1987, 1990a; Dretske 1981), the meaning of an atomic predicate may consist in its potential to get tokened in the presence of (or, in causal response to) something that instantiates the property the predicate is said to express. A natural way of explicating this potential may partly but ultimately rely on certain computational principles the symbol may be subjected to within a LOT framework, or principles that in some sense govern the "behavior" of the symbol. Insofar as computation is naturalistically understood in the way LOTH proposes, a complete answer to the first question about the semantics of atomic symbols may plausibly involve an explicatory appeal to computation within a system of symbols. This is the weak version because it doesn't see LOTH as proposing a complete solution to the first question (1) above, but only *helping* it.

A strong version would have it that LOTH provides a *complete* naturalistic solution to both questions: given the resources of LOTH we don't need to look any further to meet Brentano's challenge. The basic idea lies in so-called functional or conceptual role semantics, according to which a concept is the concept it is precisely in virtue of the particular causal/functional potential it has in interacting with other concepts. Each concept may be thought of as having a certain distinctive set of epistemic/semantic relations or liaisons to other concepts. We can conceive of this set as determining a certain "conceptual role" for each concept. We can then take these roles to determine the semantic identity of concepts: concepts are the concepts they are because they have the conceptual roles they have; that is to say, among other things, concepts represent whatever they do precisely in virtue of these roles. The idea then is to reduce each *conceptual* role to *causal/functional* role of atomic symbols (now conceived as primitive terms in LOTH), and then use the resources of LOTH to reduce it in turn to *computational* role. Since computation is naturalistically well-defined, the argument goes, and since causal interactions between thoughts and concepts can be understood completely in terms of computation, we can completely naturalize intentionality if we can successfully treat meanings as arising out of thoughts/concepts' internal interactions with each other. In other words, the strong version of LOTH would claim that atomic symbols in LOT have the content they do in virtue of their potential for causal interactions with other tokens, and cashing out this potential in mechanical/naturalistic terms is what, among other things, LOTH is for. LOTH then comes as a naturalistic rescuer for conceptual role semantics.

It is not clear whether any one holds this strong version of LOTH in this rather naive form. But certainly some people have elaborated the basic idea in quite subtle ways, for which Cummins (1989: chp.8) is perhaps the best example. (But also see Block 1986 and Field 1978.) But even in the best hands, the proposal turns out to be very problematic and full of difficulties nobody seems to know how to straighten out. In fact, some of the most ardent critics of taking LOTH as incorporating a functional role semantics turn out to be some of the most ardent defenders of LOTH understood in a weak, non-committal sense we have explored above -- see Fodor (1987: chp.3), Fodor and Lepore (1991), Fodor's attack (1978b) on AI's

way of doing procedural semantics is also relevant here. Haugeland (1981), Searle (1980, 1984), and Putnam (1988) quite explicitly take LOTH to involve a program for providing a complete semantic account of mental symbols, which they then attack accordingly.[19]

As indicated previously, LOTH is almost completely silent about consciousness and the problem of qualia, the third mystery in Fodor's list in the quote above. But the naturalist's hope is that this problem too will be solved, if not by LOTH, then by something else. On the other hand, it is important to emphasize that LOTH is neutral about the naturalizability of consciousness/qualia. If it turns out that qualia cannot be naturalized, this would by no means show that LOTH is false or defective in some way. In fact, there are people who *seem* to think that LOTH may well turn out to be true even though qualia can perhaps not be naturalized (e.g., Block 1980, Chalmers 1996, McGinn 1991).

Finally, it should be emphasized that LOTH has no particular commitment to every symbolic activity's being conscious. Conscious thoughts and thinking may be the tip of a computational iceberg. Nevertheless, there are ways in which LOTH can be helpful for an account of state consciousness that seeks to explain a thought's being conscious in terms of a higher order thought which is about the first order thought. So, to the extent to which thought and thinking are conscious, to that extent LOTH can perhaps be viewed as providing some of the necessary resources for a naturalistic account of state consciousness -- for elaboration see Rosenthal (1997) and Lycan (1997).

Arguments for LOTH

We have already seen two major arguments, perhaps the historically most important ones, for LOTH: First, we have noted that if LOTH is true then all the essential features of the common sense conception of propositional attitudes will be explicated in a naturalistic framework which is likely to be co-opted by scientific cognitive psychology, thus vindicating folk psychology. Second, we discussed that, if true, LOTH would solve one of the mysteries about thinking minds: how is thinking (as characterized above) possible? How is rationality mechanically possible? Then we have also seen a third argument that LOTH would partially contribute to the project of naturalizing intentionality by offering an account of how the semantic properties of whole attitudes are fixed on the basis of their atomic constituents. But there have been many other arguments for LOTH. In this section, I will try to describe only those arguments that have been historically more influential and controversial.

Argument from Contemporary Cognitive Psychology

When Fodor first formulated LOTH with significant elaboration in his (1975), he introduced his major argument for it along with its initial formulation in the first chapter. It was basically this: our best scientific theories and models of different aspects of higher cognition assume a framework that requires a computational/representational medium for them to be true. More specifically, he analyzes the basic form of the information processing models developed to account for three types of cognitive phenomena: *perception* as the fixation of perceptual beliefs, *concept learning* as hypothesis formation and confirmation, and *decision making* as a form of representing and evaluating the consequences of possible

actions carried out by the agent in a situation with a preordered set of preferences. He rightly points out that all these models treat mental processes as computational processes defined over representations. Then he draws what seems to be the obvious conclusion: if these models are right in at least treating mental processes as computational, even if not in detail, then there must be a LOT over which they are defined, hence LOTH.

In Fodor's (1975), the arguments for different aspects of LOTH are diffused and the emphasis, with the book's slogan "no computation without representation", is put on the RTM rather than on (B) or (C). But all the elements are surely there.

Argument from the Productivity of Thought

People seem to be capable of entertaining an infinite number of thoughts, at least in principle, although they in fact entertain only a finite number of them. Indeed adults who speak a natural language are capable of understanding sentences they have never heard uttered before. Here is one: there is a big lake of melted gold on the dark side of the moon. I bet that you never heard this sentence before, and yet, you have no difficulty in understanding it: it is one you're in fact likely to believe false. But this sentence was arbitrary, there are infinitely many such sentences I can in principle utter and you can in principle understand. But understanding a sentence is to entertain the thought/proposition it expresses. So there are in principle infinitely many thoughts you are capable of entertaining. This is sometimes expressed by saying that we have an unbounded *competence* in entertaining different thoughts, even though we have a bounded *performance*. But this unbounded capacity is to be achieved by finite means. For instance, storing an infinite number of representations in our heads is out of the question: we are finite beings. If human cognitive capacities (capacities to entertain an unbounded number of thoughts, or to have attitudes towards an unbounded number of propositions) are productive in this sense, how is this to be explained on the basis of finitary resources?

The explanation LOTH offers is straightforward: postulate a representational system that satisfies at least (B1). Indeed, recursion is the only known way to produce an infinite number of symbols from a finite base. In fact, given LOTH, productivity of thought as a competence mechanism seems to be guaranteed.[20]

Argument from the Systematicity and Compositionality of Thought

Systematicity of thought consists in the empirical fact that the ability to entertain certain thoughts is intrinsically connected to the ability to entertain certain others. Which ones? Thoughts that are related in a certain way. In what way? There is a certain initial difficulty in answering such questions. I think, partly because of this, Fodor (1987) and Fodor and Pylyshyn (1988), who are the original defenders of this kind of argument, first argue for the systematicity of language production and understanding: the ability to produce/understand certain sentences is intrinsically connected to the ability to produce/understand certain others. Given that a mature speaker is able to produce/understand a certain sentence in her native language, by psychological law, there always appear to be a cluster of other sentences that she is able to

produce/understand. For instance, you don't seem to find speakers who know how to express in their native language the fact that John loves the girl but not the fact that the girl loves John. This is apparently so, moreover, for expressions of any n-place relation.

Fodor and Pylyshyn bring out the force of this psychological fact by comparing learning languages the way we actually do with learning a language by memorizing a huge phrase book. In the phrase book model, there is nothing to prevent someone learning how to say ‘John loves the girl’ without learning how to say ‘the girl loves John.’ In fact, that is exactly the way some information booklets prepared for tourists help them to cope with their new social environment. You might, for example, learn from a phrase book how to say ‘I'd like to have a cup of coffee with sugar and milk’ in Turkish without knowing how to say/understand absolutely anything else in Turkish. In other words, the phrase book model of learning a language allows arbitrarily punctate linguistic capabilities. In contrast, a speaker's knowledge of her native language is not punctate, it is *systematic*. Accordingly, you do not find, by nomological necessity, native speakers whose linguistic capacities are punctate.

Now, how is this empirical truth (in fact, a law-like generalization) to be explained? Obviously if this is a general nomological fact, then learning one's native language cannot be modeled on the phrase book model. What is the alternative? The alternative is well known. Native speakers master the grammar and vocabulary of their language. But this is just to say that sentences are not atomic, but have syntactic constituent structure. If you have a vocabulary, the grammar tells you how to combine *systematically* the words into sentences. Hence, in this way, if you know how to construct a particular sentence out of certain words, you automatically know how to construct many others. If you view all sentences as atomic, then, as Fodor and Pylyshyn say, the systematicity of language production/understanding is a mystery, but if you acknowledge that sentences have syntactic constituent structure, systematicity of linguistic capacities is what you automatically get; it is guaranteed. This is the orthodox explanation of linguistic systematicity.

From here, according to Fodor and Pylyshyn, establishing the systematicity of thought as a nomological fact is one step away. If it is a law that the ability to understand a sentence is systematically connected to the ability to understand many others, then it is similarly a law that the ability to think a thought is systematically connected to the ability to think many others. For to understand a sentence is just to think the thought/proposition it expresses. Since, according to RTM, to think a certain thought is just to token a representation in the head that expresses the relevant proposition, the ability to token certain representations is systematically connected to the ability to token certain others. But then, this fact needs an adequate explanation too. The classical explanation LOTH offers is to postulate a system of representations with combinatorial syntax exactly as in the case of the explanation of the linguistic systematicity. This is what (B1) offers.[21] This seems to be the only explanation that does not make the systematicity of thought a miracle, and thus argues for the LOT hypothesis.

However, thought is not only systematic but also compositional: systematically connected thoughts are also always semantically related in such a way that the thoughts so related seem to be composed out of the same semantic elements. For instance, the ability to think ‘John loves the girl’ is connected to the ability to think ‘the girl loves John’ but not to, say, ‘protons are made up of quarks’ or to ‘2+2=4.’ Why is this

so? The answer LOTH gives is to postulate a combinatorial semantics in addition to a combinatorial syntax, where an atomic constituent of a mental sentence makes (approximately) the same semantic contribution to any complex mental expression in which it occurs. This is what Fodor and Pylyshyn call ‘the principle of compositionality’.[22]

In brief, it is an argument for LOTH that it offers a cogent and principled solution to the systematicity and compositionality of cognitive capacities by postulating a system of representations that has a combinatorial syntax *and* semantics, i.e., a system of representations that satisfies at least (B1).

Argument from the Systematicity of Thinking (Inferential Coherence)

Systematicity of thought does not seem to be restricted solely to the systematic ability to entertain certain *thoughts*. If the system of mental representations does have a combinatorial syntax, then there is a set of rules, syntactic formation rules, so to speak, that govern the construction of well-formed expressions in the system. It is this fact, (B1), that guarantees that if you can form a mental sentence on the basis of certain rules, then you can also form many others on the basis of the same rules. The rules of combinatorial syntax determine the syntactic or formal structure of complex mental representations. This is the *formative* (or, *formational*) aspect of systematicity. But inferential *thought processes* seem to be systematic too: the ability to make certain inferences is intrinsically connected to the ability to make certain many others. For instance, you do not find minds that can infer ‘*A*’ from ‘*A&B*’ but cannot infer ‘*C*’ from ‘*A&B&C*.’ It seems to be a psychological fact that inferential capacities come in clusters that are homogeneous in certain aspects. How is this fact (i.e., the *inferential* or *transformational* systematicity) to be explained?

As we have seen, the explanation LOTH offers depends on the exploitation of the notion of logical form or syntactic structure determined by the combinatorial syntax postulated for the representational system. The combinatorial syntax not only gives us a criterion of well-formedness for mental expressions, but it also defines the logical form or syntactic structure for each well-formed expression. The classical solution to inferential systematicity is to make the mental operations on representations sensitive to their form or structure, i.e. to insist on (B2). Since, from a syntactic view point, similarly formed expressions will have similar forms, it is possible to define a single operation which will apply to only certain expressions that have a certain form, say, only to conjunctions, or disjunctions. This allows the LOT theorist to give homogeneous explanations of what appear to be homogeneous classes of inferential capacities. This is one of the greatest virtues of LOTH, hence provides an argument for it.

The solution LOTH offers for what I called the problem of thinking, above, is connected to the argument here because the two phenomena are connected in a deep way. Thinking requires that the logico-semantic properties of a particular thought process (say, inferring that John is happy from knowing that if John is at the beach then John is happy and coming to realize that John is indeed at the beach) be somehow causally implicated in the process. The systematicity of inferential thought processes then is based on the observation that if the agent is capable of making *that* particular inference, then she is capable of making

many other somehow similarly organized inferences. But the idea of similar organization in this context seems to demand some sort of classification of thoughts independently of their *particular* content. But what can the basis of such a classification be? The only basis seems to be the logico-syntactic properties of thoughts, their form. Although it feels a little uneasy to talk about syntactic properties of thoughts common-sensically understood, it seems that they are forced upon us by the very attempt to understand their semantic properties: how, for instance, could we explain the semantic content of the thought that if John is at the beach then he is happy without somehow appealing to its being a *conditional*? This is the point of contact between the two phenomena. Especially when the demands of naturalism are added to this picture, inferring a LOT (= a representational system satisfying B) realized in the brain becomes almost irresistible. Indeed Rey (1995) doesn't resist and claims that, given the above observations, LOTH can be established on the basis of arguments that are not "merely empirical". I leave it to the reader to evaluate whether mere critical reflection on our concepts of thought and thinking could, all by itself, establish LOTH.[23]

Objections to LOTH

There have been numerous arguments against LOTH. Some of them are directed more specifically against the Representational Theory of Mind (A), some against functionalist materialism (C). Here I will concentrate only on those arguments specifically targeting (B) -- the most controversial component of LOTH.

Regress Arguments against LOTH

These arguments rely on the explanations offered by LOTH defenders for certain aspects of natural languages. In particular, many LOT theorists advert to LOTH to explain (1) how natural languages are learned, (2) how natural languages are understood, or (3) how the utterances in such languages can be meaningful. For instance, according to Fodor (1975), natural languages are learned by forming and confirming hypotheses about the translation of natural language sentences into Mentalese such as: ‘Snow is white’ is true in English if and only if *P*, where ‘*P*’ is a sentence in one's LOT. But to be able to do that, one needs a representational medium in which to form and confirm hypotheses. The LOT is such a medium. Again, natural languages are understood because, roughly, such an understanding consists in translating their sentences into one's Mentalese. Similarly, natural language utterances are meaningful in virtue of the meanings of corresponding Mentalese sentences.

The basic complaint is that in each of these cases, either the explanations generate a regress because the same sort of explanations ought to be given for how the LOT is learned, understood or can be meaningful, or else they are gratuitous because if a successful explanation can be given for LOT that does not generate a regress then it could and ought to be given for the natural language phenomena without introducing a LOT (see, e.g. Blackburn 1984). Fodor's response in (1975) is (1) that LOT is not learned, it's innate, (2) that it's understood in a different sense than the sense involved in natural language comprehension, and (3) that LOT sentences acquire their meanings not in virtue of another meaningful language but in a completely different way, perhaps by standing in some sort of causal relation to what they represent (see

above) or by having certain computational profiles. For many who have a Wittgensteinian bent, these replies are not likely to be very convincing. But here the issues tend to concern RTM rather than (B).

Laurence and Margolis (1997) point out that the regress arguments depend on the assumption that LOTH is introduced only to explain (1)-(3). If it can be shown that there are lots of other empirical phenomena for which the LOTH provides good explanations, then the regress arguments fail because LOTH then would not be gratuitous. In fact, as we have seen above, there are plenty of such phenomena. But still it is important to realize that the sort of explanations proposed for the understanding of one's LOT (computational use/activity of LOT sentences with certain meanings) and how LOT sentences can be meaningful (computational roles and/or nomic relations with the world) cannot be given for (1)-(3): it's unclear, for example, what it would be like to give a computational role and/or nomic relation account for the meanings of natural language utterances.

Propositional Attitudes without Explicit Representations

Dennett in his review of Fodor's (1975) has raised the following objection (cf. Fodor 1987: 21-3 for a similar discussion):

> In a recent conversation with the designer of a chess-playing program I heard the following criticism of a rival program: "it thinks it should get its queen out early." This ascribes a propositional attitude to the program in a very useful and predictive way, for as the designer went on to say, one can usefully count on chasing that queen around the board. But for all the many levels of explicit representation to be found in that program, nowhere is anything roughly synonymous with "I should get my queen out early" explicitly tokened. The level of analysis to which the designer's remark belongs describes features of the program that are, in an entirely innocent way, emergent properties of the computational processes that have "engineering reality." I see no reason to believe that the relation between belief-talk and psychological talk will be any more direct. (Dennett 1981: 107)

The objection, as Fodor (1987: 22) points out, isn't that the program has a *dispositional*, or *potential*, belief that it will get its queen out early. Rather, the program actually operates on this belief. There appear to be lots of other examples: e.g. in reasoning we pretty often follow certain inference rules like modus ponens, disjunctive syllogism, etc. without necessarily explicitly representing them.

The standard reply to such objections is to draw a distinction between rules on the basis of which Mentalese data-structures are manipulated, and the data-structures themselves (intuitively, the program/data distinction). LOTH is not committed to every rule's being explicitly represented. In fact, as a point of nomological fact, in a computational device not every rule can be explicitly represented: some *have to* be hard-wired and, thus, implicit in this sense. In other words, LOTH permits but doesn't require that rules be explicitly represented. On the other hand, data structures *have to* be explicitly represented: it is these that are manipulated formally by the rules. No causal manipulation is possible without explicit tokening of these structures. According to Fodor, if a propositional attitude is an actual episode in one's

reasoning that plays a causal role, then LOTH is committed to explicit representation of its content, which is as per (A2 and B2) causally implicated in the physical process realizing that reasoning. Dispositional propositional attitudes can then be accounted for in terms of an appropriate principle of inferential closure of explicitly represented propositional attitudes (cf. Lycan 1986).

Dennett's chess program certainly involves explicit representations of the chess board, the pieces, etc. and perhaps some of the rules. Which rules are implicit and which are explicit depend on the empirical details of the program. Pointing to the fact that there may be some rules that are emergent out of the implementation of explicit rules and data-structures does not suffice to undermine LOTH.

Explicit Representations without Propositional Attitudes

In any sufficiently complex computational system, there are bound to be many symbol manipulations with no obviously corresponding description at the level of propositional attitudes. For instance, when a multiplication program is run through a standard conventional computer, the steps of the program are translated into the computer's machine language and executed there, but at this level the operations apply to 1's and 0's with no obvious way to map them onto the original numbers to be multiplied or to the multiplication operation. So it seems that at the levels that, according to Dennett, have engineering reality there are plenty of explicit tokenings of representations with appropriate operations that don't correspond to anything like the propositional attitudes of folk psychology. In other words, there is plenty of symbolic activity which it would be wrong to say a *person* engages in. Rather, they are done by the person's subpersonal computational *components* as opposed to the person. How to rule out such cases? (cf. Fodor 1987: 23-6 for a similar discussion.)

They are ruled out by an appropriate reading of (A1) and (B1): (A1) says that the person herself must stand in an appropriate computational relation to a Mentalese sentence, which, as per (B1), has a suitable syntax and semantics. Only then, will the sentence constitute the person's having a propositional attitude. Not all explicit symbols in one's LOT will satisfy this. In other words, not every computational routine will correspond to a processing appropriately described as storage in, e.g., the "belief-box". Furthermore, as pointed out by Fodor (1987), LOTH would vindicate the common sense view of propositional attitudes if they turn out to be computational relations to Mentalese sentences. It may not be further required that every explicit representation correspond to a propositional attitude.

There have been many other objections to LOTH in recent years raised especially by connectionists: that LOT systems cannot handle certain cognitive tasks like perceptual pattern recognition, that they are too brittle and not sufficiently damage resistant, that they don't exhibit graceful degradation when physically damaged or as a response to noisy or degraded input, that they are too rigid, deterministic, so are not well-suited for modeling humans' capacity to satisfy multiple soft-constraints so gracefully, that they are not biologically realistic, and so on. For useful discussions of these and many similar objections, see Rumelhart, McClelland and the PDP Research Group (1986), Fodor and Pylyshyn (1988), Bechtel and Abrahamsen (1991), Horgan and Tienson (1996), and McLaughlin and Warfield (1994).

The Connectionism/Classicism Debate

When Jerry Fodor published his influential book, *The Language of Thought*, in (1975), he called LOTH "the only game in town." As we have seen, it was the philosophical articulation of the assumptions that underlay the new developments in "cognitive sciences" after the demise of behaviorism. Fodor argued for the truth of LOTH on the basis of the successes of the best scientific theories we had then. Indeed most of the scientific work in cognitive psychology, psycholinguistics, and AI assumed the framework of LOTH.

In the early 1980's, however, Fodor's claim that LOTH was the only game in town was beginning to be challenged by some people who were working on so-called connectionist networks. They claimed that **connectionism** offered a new and radically different alternative to classicism in modeling cognitive phenomena. The name 'classicism' has since then become to be applied to the LOTH framework. On the other hand, many classicists like Fodor thought that connectionism was nothing but a slightly more sophisticated way with which the old and long dead associationism, whose roots could be traced back to early British empiricists, was being revived. In 1988 Fodor and Pylyshyn (F&P) published a long article, "Connectionism and Cognitive Architecture: A Critical Analysis", in which they launched a formidable attack on connectionism, which largely set the terms for the ensuing debate between connectionists and classicists.

F&P's forceful criticism consists in posing a dilemma for connectionists: They either fail to explain the law-like cognitive regularities like systematicity and productivity in an adequate way or the connectionist models are nothing but mere implementation models of classical architectures; hence, they fail to provide a radically new paradigm as connectionists claim. This conclusion was also meant to be a challenge: Explain the cognitive regularities in question without postulating a LOT architecture.

First, let me present F&P's argument against connectionism in a somewhat reconstructed fashion. It will be helpful to characterize the debate by locating the issues according to the reactions many connectionists had to the premises of the argument.

F&P's Argument against Connectionism in their (1988):

> **(i)** Cognition essentially involves representational states and causal operations whose domain and range are these states; consequently, any scientifically adequate account of cognition should acknowledge such states and processes.
>
> **(ii)** Higher cognition (specifically, thought and thinking with propositional content) conceived in this way, has certain scientifically interesting properties: in particular, it is a law of nature that cognitive capacities are *productive*, *systematic,* and *inferentially coherent*.
>
> **(iii)** Accordingly, the architecture of any proposed cognitive model is scientifically adequate only if it guarantees that cognitive capacities are productive, systematic, etc. This

would amount to explaining, in the scientifically relevant and required sense, how it could be a law that cognition has these properties.

(iv) The only way (i.e. necessary condition) for a cognitive architecture to guarantee systematicity (etc.) is for it to involve a representational system for which (B) is true (see above). (Classical architectures necessarily satisfy (B).)

(v) Either the architecture of connectionist models does satisfy (B), or it does not.

(vi) If it does, then connectionist models are implementations of the classical LOT architecture and have little new to offer (i.e., they fail to compete with classicism, and thus connectionism does not constitute a radically new way of modeling cognition).

(vii) If it does not, then (since connectionism does not then guarantee systematicity, etc., in the required sense) connectionism is empirically false as a theory of the *cognitive* architecture.

(viii) Therefore, connectionism is either true as an implementation theory, or empirically false as a theory of cognitive architecture.

The notion of *cognitive architecture* assumes special importance in this debate. F&P's characterization of the notion goes as follows:

> The architecture of the cognitive system consists of the set of basic operations, resources, functions, principles, etc. (generally the sorts of properties that would be described in a "user's manual" for that architecture if it were available on a computer) whose domain and range are the *representational states* of the organism. (1988: 10)

Also, note that (B1) and (B2) are meta-architectural properties in that they are themselves conditions upon any proposed specific architecture's being classical. They define classicism per se, but not any particular way of being classical. Classicism as such simply claims that whatever the *particular* cognitive architecture of the brain might turn out to be (whatever the *specific* grammar of Mentalese turns out to be), (B) must be true of it. F&P claim that this is the only way an architecture can be said to guarantee the nomological necessity of cognitive regularities like systematicity, etc. This seems to be the relevant and required sense in which a scientific explanation of cognition is required to guarantee the regularities -- hence the third premise in their argument.

Connectionist responses have fallen into four classes:

(1) *Deny premise(i)*. The rejection of (i) commits connectionists to what is sometimes called *radical* or *eliminativist connectionism*. Premise (i), as F&P point out, draws a general line between eliminativism and representationalism (or, intentional realism). There has been

some controversy as to whether connectionism constitutes a serious challenge to the fundamental tenets of folk psychology.[24] It is too early to assess the potential of connectionism in this regard.[25] On the other hand, many connectionists do in fact advance their models as having causally efficacious representational states, and explicitly endorse F&P's first premise. So they seem to accept intentional realism.[26]

(2) *Accept the conclusion*. This group may be seen as more or less accepting the cogency of the entire argument, and characterizes itself as *implementationalist*: they hold that connectionist networks will *implement* a classical architecture or language of thought. According to this group, the appropriate niche for neural networks is closer to neuroscience than to cognitive psychology. They seem to view the importance of the program in terms of its prospects of closing the gap between the neurosciences and high-level cognitive theorizing. In this, many seem content to admit premise (vi).

(3) *Deny premise (ii) or (iv)*. Some connectionists reject (ii) or (iv),[27] holding that there are no lawlike cognitive regularities such as systematicity (etc.) to be explained, or that such regularities do not require a (B)-like architecture for their explanation. Those who question (ii) often question the empirical evidence for systematicity (etc.) and tend to ignore the challenge put forward by F&P. Those who question (iv) also often question (ii), or they argue that there can be very different sort of explanations for systematicity and the like (e.g. evolutionary explanations, see Braddon-Mitchell and Fitzpatrick 1990), or they question the very notion of explanation involved (e.g. Matthews 1994). There are indeed quite a number of different kinds of arguments in the literature against these premises.[28] For a sampling, see Aydede (1995) and McLaughlin (1993b), who partitions the debate similarly. (See also Aydede (1998), in the Other Internet Resources section of this entry.). The debate on the issues raised by these connectionists and their sympathizers is still very lively.

(4) *Deny premise (vi)*. The group of connectionists who have taken F&P's challenge most seriously has tended to reject premise (vi) in their argument, while accepting, on the face of it, the previous five premises (sometimes with reservations on the issue of productivity). They think that it is possible for connectionist representations to be syntactically structured in some sense without being classical. Prominent in this group are Smolensky (1990a, 1990b, 1995), van Gelder (1989, 1990, 1991), Chalmers (1990, 1993). Some connectionists whose models give support to this line include Elman (1989), Hinton (1990), Touretzky (1990), Pollack (1990).[29]

Much of the recent debate between connectionists and classicists has focused on this option, so let's see how it is possible to reject premise (vi), which seems true by definition of classicism. The connectionists' answer, roughly put, is that when you devise a representational system whose satisfaction of (B) relies on a *non-concatenative* realization of structural/syntactic complexity of representations, you have a non-classical system. (See especially Smolensky 1990a and van Gelder 1990.) Interestingly, some classicists like Fodor and McLaughlin (1990) (F&M) seem to agree. F&M stipulate that you have a classical system

only if the syntactic complexity of representations is realized *concatenatively*, or as it is sometimes put, *explicitly*:

> We ... stipulate that for a pair of expression types E1, E2, the first is a *Classical* constituent of the second *only if* the first is tokened whenever the second is tokened. (F&M 1990: 186)

The issues about how connectionists propose to obtain constituent sructure non-concatenatively tend to be complex and technical. But they propose to exploit so called *distributed representations* in certain novel ways. The essential idea behind most of them is to use vector (and tensor) algebra (involving superimposition, multiplication, etc. of vectors) in composing and decomposing connectionist representations which consist in coding patterns of activity across neuron-like units which can be modeled as vectors. The result of such techniques is the production of representations that have in some interesting sense a complexity whose constituent structure is largely implicit in that the constituents are not tokened explicitly when the representations are tokened, but can be recovered by further operations upon them. The interested reader should consult some of the pioneering work by Elman (1989), Hinton (1990), Smolensky (1989, 1990, 1995), Touretzky (1990), Pollack (1990).

F&M's criticism, more specifically stated, however, is this. Connectionists with such techniques only satisfy (B1) in some "extended sense", but they are incapable of satisfying (B2), precisely because their way of satisfying (B1) is committed to a non-concatenative realization of syntactic structures.

Some connectionists disagree (e.g. Chalmers 1993): they claim that you can have structure-sensitive transformations or operations defined over representations whose syntactic structure is non-concatenatively realized. So given the apparent agreement that non-concatenative realization is what makes a system non-classical, connectionists claim that they can and do perfectly satisfy (B) in its entirety with their connectionist models without implementing classical models.

The debate is still intense and there is a fast growing literature built around the many issues raised by it. Aydede (1997) offers an extensive analysis of the debate between classicists and this group of connectionists with special attention to the conceptual underpinnings of the debate. He argues that both parties are wrong in assuming that concatenative realization is relevant to the characterization of LOTH. He specifies what minimally needs to be the case for the LOTH to be true, and why.

Notes to The Language of Thought Hypothesis

Notes

1. This is to convey the basic idea that each type of attitude (e.g., believing) is realized by the same type of psychological relation (e.g., being inside the computationally defined B-Box) and by no others, for which see below. So the mapping from attitudes *A* into psychological relations *R* is meant to be injective.

2. Lycan (1986), Davies (1989, 1995), Cummins (1986), Hadley (1995). A parallel discussion is going on in AI: Kirsh (1990).

3. See Fodor (1985, 1986, 1987: chp.1), Devitt (1990).

4. But see Rey (1992, 1993) for an attempt to expand LOTH to sensations and qualia.

5. See for instance the controversy involved in the so-called imagery debate. The literature here is huge but the following sample may be useful: Block (1981, 1983b), Dennett (1978), Kosslyn (1980), Pylyshyn (1978), Rey (1981), Sterelny (1986), Tye (1991).

6. E.g., Marr (1982), or any textbook on vision or language comprehension and production.

7. E.g., Kosslyn (1980, 1994); Shepard and Cooper (1982). In fact, some theorists even go so far as to claim that *all* cognition is done in an image-like symbol system -- early British empiricists from Locke to Hume held something like this view, but more recently, see L. Barsalou and his colleagues who have been developing models to that effect (Barsalou 1993a, Barsalou et al 1993b, Barsalou and Prinz 1997).

8. The controversial issue here is not the absurdity of the claim that there are literally pictures or images in the brain. Probably no one believes this claim these days. Rather, postulating picture-like representations is to be cashed out in functionalist terms. Pictures as mental representations presumably bear some non-arbitrary isomorphisms to what they represent, although it is hard to make this sort of claim crystal-clear in purely functionalist terms. See, for instance, Kosslyn (1980, 1981), Block (1983a, 1983b), Tye (1984).

9. The issues here are too complex and difficult to go over here in any useful detail, but for a general criticism of pictures as mental representations, see the critical essays in Block (1981) and Rey (1981); for an attempt to overcome many such criticisms, see Barsalou and Prinz (1997) and Prinz (1997). The contemporary debate about the adequacy of a purely imagistic medium for capturing what is involved in

making a judgment and discursive thinking seem to parallel some of Kant's critique of British Empiricism in general and of Hume's associationism in particular, as indeed emphasized by many classicists like Fodor and Pylyshyn (1988), Rey (1997).

10. See, e.g., Barwise and Etchemendy's *Hyperproof* (1995).

11. For a non-nativist but otherwise quite Fodorian account of concept acquisition, see Margolis (forthcoming).

12. But see Rey (1992, 1993) for an attempt to extend LOTH in this direction.

13. Also, Hubert Dreyfus and John Haugeland's many writings indicate that they are realist about propositional attitudes but would reject LOTH nevertheless.

14. Almost all British empiricists might be put in this latter category too, but they were in fact closer to LOTH by having embraced something like (B1) in some imagistic version. But it looks like they could not be better than being associationist regarding *thought processes*: they could not exploit the clear implications of modern symbolic logic and the advancement of computers -- they did not have their Frege and Turing, though Hobbes came close. This rendering of RTM relies on a broad interpretation of the notion of mental representation, of course, which has not always been the intended interpretation of Fodor: there are many places where he defends RTM (by that name) meaning to include (B) by default (Fodor 1981b, 1985, 1987, 1998). This should cause no confusion. Here I have chosen to stick to the literal meaning of the phrase rather than to its historically more accurate use -- this has become necessary, at any rate, in the light of the recent classicism/connectionism debate to which we will return below.

15. For a powerful elaboration of this line of thought, see Rey (1997).

16. A number of proposals have been offered by contemporary theorists (who are not necessarily defenders of LOTH as opposed to being mere RTM theorists but whose proposals can be adapted by LOT theorists) about how exactly to pursue that project. See, for instance, Fodor (1987, 1990), Dretske (1981, 1988), Millikan (1984, 1993), Papineau (1987), Devitt (1996), Loar (1982a), Field (1972, 1978), Block (1986).

17. Tarski (1956), Field (1972), Davidson (1984).

18. Although I described the line above as official and presented it as requiring a compositional semantics, and although almost all the defenders of LOTH conceive of it in this way because they think that is what empirical facts about thought and language demand, nevertheless it is perhaps important to be pedantic about exactly what LOTH is minimally committed to. Minimally, it is *not* committed to regarding the internal code as having a compositional semantics, namely a semantics where the meaning

of complex sentences are determined by the meanings of its constituents together with their syntax; this, in effect, requires that the atomic expressions always make (approximately) the same semantic contributions to the whole of which they are constituents (idioms excepted). But strictly speaking LOTH can live without having a strictly compositional semantics if it turns out that there are other ways of explaining those empirical facts about the mind to which I will come below. Admittedly, in such a case LOTH would lose some portion of its appeal and interest. But even if this scenario turns out to be the case, there are still a lot of facts for LOTH to explain. Having said this, however, I will simply forget it in what follows.

19. For fairness I should add that Searle's and Haugeland's criticisms are directed against AI community at large, and there, it has been common to conceive the computational model of mind as potentially involving a complete solution to semantic worries among others. Thus, Haugeland termed his target ‘GOFAI’ (the Good Old Fashion Artifical Intelligence). Similarly, Searle's famous Chinese Room Argument was directed against what he called ‘Strong AI’.

20. See Fodor (1985, 1987), Fodor and Pylyshyn (1988) for an elaborate presentation of this argument for LOTH.

21. It should be noted however that (B1) is a meta-architectural condition that needs to be satisfied by any *particular* grammar for Mentalese, just as an analogue for (B1) is a condition upon the *specific* grammar of all systematic languages (see below).

22. It is somewhat confusing that Fodor and Pylyshyn called this *empirical cognitive regularity* "compositionality" of cognitive capacities. In particular, the empirical phenomenon -- i.e., the *fact* that systematically connected thoughts are also always semantically related or semantically close to each other -- that needs to be explained is explained by LOT theorists by what is also called semantic compositionality: namely, the semantic value of a complex expression is a function of the semantic value of its atomic constituents such that each atomic constituent makes approximately the same semantic contribution to the context in which it occurs. This is what the postulation of a combinatorial semantics in conjunction with a combinatorial syntax buys for LOT-theorists in adequately explaining the empirical regularity in question. See Fodor and Pylyshyn (1988: 41-5).

23. For a prioristic arguments of this sort, see also Lycan (1993) and Davies (1989, 1991).

24. For example, Patricia and Paul Churchland, who have been the champions of eliminativism, hope that connectionism is the long waited theory which will provide the scientific foundations of the elimination of folk psychological constructs in "psychology" (P.S. Churchland 1986, 1987; Churchland and Sejnowski 1989; P.M. Churchland 1990; P.S. Churchland and P.M. Churchland 1990). Ramsey, Stich and Garon (1991) have recently defended the claim that if certain sorts of connectionist models turn out to be right then the elimination of folk psychology will be inevitable. Dennett (1986), and Cummins and Schwartz (1987) have also pointed out the potential of connectionism in the elimination of at least certain aspects of folk psychology.

25.In fact, it is not clear at all, how connectionism can genuinely give support to intentional eliminativism as far as the units (or collections of units) in connectionist networks are treated as representing. If they are not treated as such, it is hard to see how they could be models of *cognitive* phenomena, and thus hard to see how they can present any eliminativist challenge. However, there appear to be two vague strands among eliminativists in this regard. One stems from the intuition that it is unlikely that there are really any concrete, isolable, and modularly identifiable symbol structures realized in the brain that would correspond to what Stich has called (1983: 237ff.) functionally discrete beliefs and desires of folk psychology, and connectionist networks, it is claimed, will vindicate this intuition. For similar remarks, among others, see Dennett (1986, 1991a), Clark (1988, 1989b). The second trend seems to be that connectionism will vindicate the claim that the explanation of mental phenomena doesn't require a full-blown semantics for such higher-order states as propositional attitudes. Rather, all that is needed is an account of some form of information processing at a much lower level, which, it is hoped, will be sufficient for the whole range of cognitive phenomena. Again, it is not clear what the proposals are. But see Paul Churchland (1990).

26. It seems clear from some of the so far proposed models that many connectionists have been developing their models ultimately with an eye to capture the generalizations in their respective psychological domain. To see this it is enough to look at some of the papers in the second PDP volume (Rumelhart, McClelland and the PDP Research Group, 1986) among which Rumelhart and McClelland's paper on modeling learning the past tenses of English verbs is particularly celebrated. At the end, it is of course an open empirical question whether connectionist models will ultimately be able to capture them, or whether the generalizations they come up with will be compatible with or be the ones implicitly recognized by the folk, just as it is an open question whether classical models will ultimately be successful in this respect. Whatever the final outcome might be, however, it is *prima facie* the case that many connectionists intend their models to be taken as contributions within the intentional realist tradition. Smolensky (1988) is the most articulated defense of something like this position. He calls his position "the Proper Treatment of Connectionism" (PTC) and clearly separates it from various eliminativist positions.

27. Premise (iii) is intimately connected to (ii) and (iv). So its rejection by itself does not mean much. Premise (iii), according to F&P, is there to prevent certain *ad hoc* solutions on the part of connectionists in the explanation of cognitive regularities mentioned in (ii). Premise (v) is close to being a tautology. So no one has any quarrel with it, although van Gelder (1991) comes very close to rejecting it on the ground that with every shift in scientific paradigms the conceptual apparatus of the previous and challenged paradigms becomes inadequate to correctly characterize the new and challenging paradigm.

28. Some people who object to (ii) or (iv) are Dennett (1991b), Sterelny (1990), Rumelhart and McClelland (1986), Clark (1989b, 1991), Braddon-Mitchell and Fitzpatrick (1990), Butler (1991), Matthew (1994), Aizawa (forthcoming), Garson (forthcoming) and Wallis (forthcoming).

29. Smolensky, for instance, is very explicit in his rejection of premise (vi): " ...distributed connectionist

architectures, without implementing the Classical architecture, can nonetheless provide structured mental representations and mental processes sensitive to that structure" (1990a: 215) .

The Church-Turing Thesis

There are various equivalent formulations of the Church-Turing thesis. A common one is that every effective computation can be carried out by a Turing machine. The Church-Turing thesis is often misunderstood, particularly in recent writing in the philosophy of mind.

The Thesis and its History

The Church-Turing thesis concerns the notion of an *effective* or *mechanical* method in logic and mathematics. 'Effective' and its synonym 'mechanical' are terms of art in these disciplines: they do not carry their everyday meaning. A method, or procedure, M, for achieving some desired result is called 'effective' or 'mechanical' just in case

1. M is set out in terms of a finite number of exact instructions (each instruction being expressed by means of a finite number of symbols);
2. M will, if carried out without error, always produce the desired result in a finite number of steps;
3. M can (in practice or in principle) be carried out by a human being unaided by any machinery save paper and pencil;
4. M demands no insight or ingenuity on the part of the human being carrying it out.

A well-known example of an effective method is the truth table test for tautologousness. In practice, of course, this test is unworkable for formulae containing a large number of propositional variables, but in principle one could apply it successfully to any formula of the propositional calculus, given sufficient time, tenacity, paper, and pencils.

Statements that there is an effective method for achieving such-and-such a result are commonly expressed by saying that there is an effective method for obtaining the values of such-and-such a mathematical function. For example, that there is an effective method for determining whether or not any given formula of the propositional calculus is a tautology - e.g. the truth table method - is expressed in function-speak by saying that there is an effective method for obtaining the values of a function, call it T, whose domain is the set of formulae of the propositional calculus and whose value for any given formula x, written T(x), is 1 or 0 according to whether x is, or is not, a tautology.

The notion of an effective method is an informal one, and attempts to characterise effectiveness, such as the above, lack rigour, for the key requirement that the method demand no insight or ingenuity is left unexplicated. One of Turing's achievements in his paper of 1936 was to present a formally exact predicate with which the informal predicate 'can be calculated by means of an effective method' may be replaced. Church did the same (1936a). The replacement predicates that Turing and Church proposed were, on the face of it, very different from one another, but they turned out to be equivalent, in the sense that each picks out the same set of mathematical functions. The Church-Turing thesis is the assertion that this set contains every function whose values can be obtained by a method satisfying the above conditions for effectiveness. (Clearly, if there were functions of which the informal predicate, but not the formal predicate, were true, then the latter would be less general than the former and so could not reasonably be employed to replace it.) When the thesis is expressed in terms of the formal concept proposed by Turing, it is appropriate to refer to the thesis also as 'Turing's thesis'; and mutatis mutandis in the case of Church.

The formal concept proposed by Turing is that of *computability by Turing machine*. He argued for the claim (Turing's thesis) that whenever there is an effective method for obtaining the values of a mathematical function, the function can be computed by a Turing machine. The converse claim is easily established, for a Turing machine program is itself a specification of an effective method: a human being can work through the instructions in the program and carry out the operations called for without the exercise of any ingenuity or insight. If Turing's thesis is correct then talk about the existence and non-existence of effective methods can be replaced throughout mathematics and logic by talk about the existence or non-existence of Turing machine programs.

Turing stated his thesis in numerous places, with varying degrees of rigour. The following formulation is one of the most accessible.

> **Turing's thesis**: LCMs [logical computing machines: Turing's expression for Turing machines] can do anything that could be described as "rule of thumb" or "purely mechanical". (Turing 1948:7.)

He adds:

> This is sufficiently well established that it is now agreed amongst logicians that "calculable by means of an LCM" is the correct accurate rendering of such phrases. (Ibid.)

Turing introduced this thesis in the course of arguing that the Entscheidungsproblem, or decision problem, for the predicate calculus - posed by Hilbert (Hilbert and Ackermann 1928) - is unsolvable. Here is Church's account of the Entscheidungsproblem:

> By the Entscheidungsproblem of a system of symbolic logic is here understood the problem to find an effective method by which, given any expression Q in the notation of the system, it can be determined whether or not Q is provable in the system. (Church 1936b: 41.)

The truth table test is such a method for the propositional calculus. Turing showed that, given his thesis, there can be no such method for the predicate calculus. He proved formally that there is no Turing machine which can determine, in a finite number of steps, whether or not any given formula of the predicate calculus is a theorem of the calculus. So, given his thesis that if an effective method exists then it can be carried out by one of his machines, it follows that there is no such method to be found.

Church had arrived at the same negative result a few months earlier, employing the concept of lambda-definability in place of computability by Turing machine. Church and Turing discovered the result quite independently of one another. Turing's method of obtaining it is rather more satisfying than Church's, as Church himself acknowledged in a review of Turing's work:

> computability by a Turing machine ... has the advantage of making the identification with effectiveness in the ordinary (not explicitly defined) sense evident immediately. (1937a: 43.)

(Another aspect in which their approaches differ is that Turing's concerns were rather more general than Church's, in that the latter considered only functions of positive integers (see below), whereas Turing described his work as encompassing "computable functions of an integral variable or a real or computable variable, computable predicates, and so forth" (1936: 230). He intended to pursue the theory of computable functions of a real variable in a subsequent paper, but in fact did not do so.)

Church used the (informal) expression 'effectively calculable' to indicate that there is an effective method for calculating the values of the function. He proposed that we

> define the notion ... of an effectively calculable function of positive integers by identifying it with the notion of a recursive function of positive integers (or of a lambda-definable function of positive integers). (1936a: .)

The concept of a lambda-definable function is due to Church and Kleene (Church 1932, 1936a, 1941, Kleene 1935) and the concept of a recursive function to Gödel and Herbrand (Gödel 1934, Herbrand 1932). The class of lambda-definable functions and the class of recursive functions are identical. This was established in the case of functions of positive integers by Church and Kleene (Church 1936a, Kleene 1936). After learning of Church's proposal, Turing quickly established that the apparatus of lambda-definability and his own apparatus of computability are equivalent (1936: 263ff). Thus, in Church's

proposal, the words ‘recursive function of positive integers’ can be replaced by the words ‘function of positive integers computable by Turing machine’.

Post referred to Church’s identification of effective calculability with recursiveness as a "working hypothesis", and quite properly criticised Church for masking this hypothesis as a definition.

> [T]o mask this identification under a definition ... blinds us to the need of its continual verification. (Post 1936: 105.)

This, then, is the "working hypothesis" that, in effect, Church proposed:

> **Church’s thesis**: A function of positive integers is effectively calculable only if recursive.

The reverse implication, that every recursive function of positive integers is effectively calculable, is commonly referred to as *the converse of Church’s thesis* (although Church himself did not so distinguish, bundling both theses together in his ‘definition’). If attention is restricted to functions of positive integers then Church’s thesis and Turing’s thesis are equivalent, in view of the previously mentioned results by Church, Kleene and Turing.

The term ‘Church-Turing thesis’ seems to have been first introduced by Kleene, with a small flourish of bias in favour of Church:

> So Turing’s and Church’s theses are equivalent. We shall usually refer to them both as *Church’s thesis*, or in connection with that one of its ... versions which deals with ‘Turing machines’ as *the Church-Turing thesis*. (Kleene 1967: 232.)

Much evidence has been amassed for the ‘working hypothesis’ proposed by Church and Turing in 1936. Perhaps the fullest survey is to be found in chapters 12 and 13 of Kleene (1952). In summary: (1) Every effectively calculable function that has been investigated in this respect has turned out to be computable by Turing machine. (2) All known methods or operations for obtaining new effectively calculable functions from given effectively calculable functions are paralleled by methods for constructing new Turing machines from given Turing machines. (3) All attempts to give an exact analysis of the intuitive notion of an effectively calculable function have turned out to be equivalent in the sense that each analysis offered has been proved to pick out the same class of functions, namely those that are computable by Turing machine. Because of the diversity of the various analyses the latter is generally considered strong evidence. For example, apart from the analyses already mentioned in terms of lambda-definability and recursiveness, there are analyses in terms of register machines (Shepherdson and Sturgis 1963), Post’s canonical and normal systems (Post 1943, 1946), combinatory definability (Schönfinkel 1924, Curry 1929, 1930, 1932), Markov algorithms (Markov 1960), and Gödel’s notion of reckonability (Gödel 1936, Kleene 1952).

While there have from time to time been attempts to call the Church-Turing thesis into question (for

example by Kalmar (1959); Mendelson (1963) replies), the summary of the situation that Turing gave in 1948 is no less true today: "it is now agreed amongst logicians that ‘calculable by means of an LCM’ is the correct accurate rendering" (of the informal notion in question).

Misunderstandings of the Thesis

A myth has arisen concerning Turing’s paper of 1936, namely that he there gave a treatment of, and established fundamental results concerning, the limits of what can be computed by machine - a myth that has passed into the philosophy of mind, to wide and pernicious effect. For example, the *Oxford Companion to the Mind* states: "Turing showed that his very simple machine ... can specify the steps required for the solution of any problem that can be solved by instructions, explicitly stated rules, or procedures" (Gregory 1987: 784). Dennett maintains that "Turing had proven - and this is probably his greatest contribution - that his Universal Turing machine can compute any function that any computer, with any architecture, can compute" (1991: 215). Sterelny asserts "Astonishingly, Turing was able to show that any procedure that can be computed at all can be computed by a Turing machine. ... Despite their simple organisation, Turing machines are, in principle, as powerful as any other mode of organizing computing systems" (1990: 37, 238). In similar vein, Paul Churchland writes: "The interesting thing about a universal Turing machine is that, *for any well-defined computational procedure whatever, a universal Turing machine is capable of simulating a machine that will execute those procedures*. It does this by reproducing exactly the input/output behaviour of the machine being simulated" (1988:105). Also: Turing’s "results entail something remarkable, namely that a standard digital computer, given only the right program, a large enough memory and sufficient time, can compute *any* rule-governed input-output function. That is, it can display any systematic pattern of responses to the environment whatsoever" (Paul and Patricia Churchland 1990: 26). These various quotations are typical of current writing on the foundations of the computational theory of mind.

Turing did not show that his machines can solve any problem that can be solved "by instructions, explicitly stated rules, or procedures" and nor did he prove that a universal Turing machine "can compute any function that any computer, with any architecture, can compute". He proved that his universal machine can compute any function that any *Turing machine* can compute; and he put forward, and advanced philosophical arguments in support of, the thesis here called Turing’s thesis. But a thesis concerning the extent of effective methods - which is to say, concerning the extent of procedures of a certain sort that a *human being unaided by machinery* is capable of carrying out - carries no implication concerning the extent of the procedures that machines are capable of carrying out, even machines acting in accordance with ‘explicitly stated rules’. For among a machine’s repertoire of atomic operations there may be those that no human being unaided by machinery can perform.

The further proposition, very different from Turing’s own thesis, that a Turing machine can compute whatever can be computed *by any machine working on finite data in accordance with a finite program of instructions* is nowadays sometimes referred to as the Church-Turing thesis or as Church’s thesis. For example, Smolensky says:

> connectionist models ... may possibly even challenge the strong construal of Church's Thesis as the claim that the class of well-defined computations is exhausted by those of Turing machines. (Smolensky 1988: 3.)

This loosening of established terminology is unfortunate, for neither Church nor Turing endorsed, or even formulated, this further proposition. There are numerous examples of this extended usage in the literature. The following are typical.

> [T]he work of Church and Turing fundamentally connects computers and Turing machines. The limits of Turing machines, according to the Church-Turing thesis, also describe the theoretical limits of all computers. (McArthur 1991: 401.)

> [The] Church/ Turing thesis ... equates the mathematically precise notion of "solvable by a Turing machine" with the informal, intuitive notion of "solvable effectively", which alludes to all real computers and all programming languages, those that we know about at present as well as those that we do not. (Harel 1992: 233.)

> The Church-Turing thesis makes a bold claim about the theoretical limits to computation. (Cleland 1993: 283.)

Also (more distant still from anything that Church or Turing actually wrote):

> The first aspect that we examine of Church's Thesis ... [w]e can formulate, more precisely: The behaviour of any discrete physical system evolving according to local mechanical laws is recursive. (Odifreddi 1989: 107.)

> I can now state the physical version of the Church-Turing principle: "Every finitely realizable physical system can be perfectly simulated by a universal model computing machine operating by finite means." This formulation is both better defined and more physical than Turing's own way of expressing it. (Deutsch 1985: 99.)

Gandy (1980) is one of the few writers to distinguish explicitly between Turing's thesis and the stronger proposition that whatever can be calculated by a machine can be calculated by a Turing machine. Borrowing Gandy's terminology, I will call the stronger proposition 'Thesis M'. I will use expressions such as 'the Church-Turing thesis properly so-called' for the proposition that Church and Turing themselves endorsed.

> **Thesis M**: Whatever can be calculated by a machine (working on finite data in accordance with a finite program of instructions) is Turing-machine-computable.

Thesis M itself admits of two interpretations, according to whether the phrase 'can be calculated by a machine' is taken in the narrow sense of 'can be calculated by a machine that conforms to the physical

laws (if not to the resource constraints) of the actual world', or in a wide sense that abstracts from the issue of whether or not the notional machine in question could exist in the actual world. The narrow version of thesis M is an empirical proposition whose truth-value is unknown. The wide version of thesis M is known to be false. Various notional machines have been described which can calculate functions that are not Turing-machine-computable (for example, Abramson (1971), da Costa and Doria (1991), (1994), Doyle (1982), Hogarth (1994), Pour-El and Richards (1979), (1981), Scarpellini (1963), Siegelmann and Sontag (1994), Stannett (1990), Stewart (1991); Copeland and Sylvan (1997) is a survey).

The literature on the computational theory of the mind contains numerous endorsements of propositions equivalent or similar to thesis M that are supported by nothing more than a reference to the work of Turing or Church (as is illustrated by a number of the quotations given earlier). Perhaps some writers are simply misled by the terminological practice that has grown up whereby a thesis concerning which there is little real doubt, the Church-Turing thesis properly so-called, and a different thesis of unknown truth-value, are referred to indiscriminately as Church's thesis or the Church-Turing thesis (albeit with accompanying hedges like 'strong form' and 'physical version'). Some - Dennett and Sterelny, for example - think themselves entitled to endorse the stronger proposition because they believe that, somehow, Turing proved it. Other writers maintain thesis M (or some equivalent or near equivalent) on the spurious ground that the various and prima facie very different attempts - by Turing, Church, Post, Markov, and others - to characterise in precise terms the informal notion of an effective procedure have turned out to be equivalent to one another. This is evidence concerning the extent of effective procedures, and not evidence concerning the extent of what can be calculated by machine or organ.

This simple error of confusing the Church-Turing thesis properly so-called with thesis M has led to some remarkable claims in the foundations of psychology. For example, Boden insists that "If a psychological science is possible at all, it must be capable of being expressed in computational terms " (Boden 1988: 259). This is presumably false. The possibility that psychological science will in the future find need to employ mathematical functions that are *not* Turing-machine-computable cannot be ruled out. Boden's reason for thinking her claim true is (she says) her belief that "Alan Turing ... *proved* that a language capable of defining 'effective procedures' suffices, in principle, to solve any computable problem" (ibid.;the italics are Boden's).

It is important to note that in the technical literature the word 'computable' is often tied *by definition* to effective calculability. Thus a function is said to be computable if and only if there is an effective procedure for determining its values. Accordingly, a common formulation of the Church-Turing thesis in the technical literature and in textbooks is:

> All computable functions are computable by Turing machine.

Corollaries such as the following are sometimes offered:

> certain functions are uncomputable in an absolute sense: uncomputable even by [Turing machine], and, therefore, uncomputable by any past, present, or future real machine.

> (Boolos and Jeffrey 1980: 55.)

Given this definition of ‘computable’, the Church-Turing thesis does entail that if a function f is not computable by Turing machine then it is not computable by any machine (for if f is not computable by Turing machine then, by the thesis, there is no effective procedure for determining f’s values, and so f is not computable). Of course, a terminological decision like this cannot settle the truth-value of thesis M; rather, those who abide by this decision are prevented from describing any machines that falsify thesis M as *computing*. Yet to a casual reader of the literature, statements like the one just quoted may appear to say more than they in fact do.

The word ‘mechanical’, too, in technical usage, is tied to effectiveness and, as already remarked, ‘mechanical’ and ‘effective’ are used interchangeably. (Gandy (1988) outlines the history of this usage of the word ‘mechanical’.) Thus statements like the following are to be found in the technical literature:

> Turing proposed that a certain class of abstract machines could perform any ‘mechanical’ computing procedure. (Mendelson 1964: 229.)

Understood correctly, this remark attributes to Turing not thesis M but the Church-Turing thesis. This usage of ‘mechanical’ tends to obscure the possibility that there may be machines, or biological organs, that calculate (or compute, in a broad sense) functions that are not Turing-machine-computable. For the question ‘Can a machine execute a procedure that is not mechanical?’ may appear self-answering, yet this is precisely what is asked if thesis M is questioned.

An error which, unfortunately, is common in modern writing on computability and the brain is to hold that Turing’s results somehow entail that the brain, and indeed any biological or physical system whatever, can be *simulated* by a Turing machine. For example, the entry on Turing in the recent *A Companion to the Philosophy of Mind* contains the following claims: "we can depend on there being a Turing machine that captures the functional relations of the brain", for so long as "these relations between input and output are functionally well-behaved enough to be describable by ... mathematical relationships ... we know that some specific version of a Turing machine will be able to mimic them" (Guttenplan 1994: 595). Searle writes in a similar fashion:

> Can the operations of the brain be simulated on a digital computer? ... The answer seems to me ... demonstrably ‘Yes’ ... That is, naturally interpreted, the question means: Is there some description of the brain such that under that description you could do a computational simulation of the operations of the brain. But given Church’s thesis that anything that can be given a precise enough characterization as a set of steps can be simulated on a digital computer, it follows trivially that the question has an affirmative answer. (Searle 1992: 200.)

So too Johnson-Laird, and the Churchlands:

> If you assume that [consciousness] is scientifically explicable ... [and] [g]ranted that the [Church-Turing] thesis is correct, then ... [i]f you believe [functionalism] to be false ... then ... you [should] hold that consciousness could be modelled in a computer program in the same way that, say, the weather can be modelled ... [and if] you accept functionalism ... you should believe that consciousness is a computational process. (Johnson-Laird 1987: 252.)

> Church's Thesis says that whatever is computable is Turing computable. Assuming, with some safety, that what the mind-brain does is computable, then it can in principle be simulated by a computer. (Churchland and Churchland 1983: 6.)

As previously mentioned, Churchland and Churchland believe, erroneously, that Turing's "results entail ... that a standard digital computer, given only the right program, a large enough memory and sufficient time, can ... display any systematic pattern of responses to the environment whatsoever" (1990: 26). This no doubt explains why they think they can assume "with some safety" that what the mind-brain does is computable, for on their understanding of matters this is to assume only that the mind-brain exhibits a systematic pattern of responses, or is characterised by a 'rule-governed' (1990: 26) input-output function.

The Church-Turing thesis does not entail that the brain (or the mind, or consciousness) can be modelled by a Turing machine program, not even in conjunction with the belief that the brain (or mind, etc.) is scientifically explicable, or exhibits a systematic pattern of responses to the environment, or is 'rule-governed' (etc.). Each of the authors quoted seems to be assuming the truth of a close cousin of thesis M, which I will call

> **Thesis S**: Any process that can be given a systematic mathematical description (or a 'precise enough characterization as a set of steps', or that is scientifically describable or scientifically explicable) can be simulated by a Turing machine.

As with thesis M, neither the Church-Turing thesis properly so-called nor any result proved by Turing or Church entails thesis S. This is so even when the thesis is taken narrowly, as concerning processes that conform to the physics of the real world. (Thesis S taken in the wide sense is known to be false; see the references given earlier re the wide version of thesis M.) Any device or organ whose internal processes can be described completely *by means of effectively calculable functions* can be simulated exactly by a Turing machine program (provided that the input into the device or organ is itself Turing-machine-computable, which is to say, is either finite or expressible as a computable number, in Turing's sense (which is explained below)); but any device or organ whose mathematical description involves functions that are not effectively calculable cannot be so simulated. As Turing showed, there are uncountably many such functions. (Examples from logic are Turing's famous halting function (described in the entry on Turing machines) and the function D whose domain is the set of well-formed formulae of the predicate calculus and whose values, D(x), are 1 or 0 according to whether x is, or is not, derivable from the Bernays-Hilbert-Ackermann axioms for predicate logic.) It is an open question whether a completed neuroscience will employ functions that are not effectively calculable.

Some Key Remarks by Turing

Turing introduces his machines with the intention of providing an idealised description of a certain human activity, the tedious one of *numerical computation*, which until the advent of automatic computing machines was the occupation of many thousands of people in commerce, government, and research establishments. He prefaces his first description of a Turing machine with the words:

> We may compare a man in the process of computing a ... number to a machine. (Turing 1936: 231.)

The Turing machine is a model, idealised in certain respects, of a human being engaged in computation. Wittgenstein put this point in a striking way:

> Turing's "Machines". These machines are *humans* who calculate. (Wittgenstein 1980, 1096.)

It is a point that Turing was to emphasise, in various forms, again and again. For example:

> A man provided with paper, pencil, and rubber, and subject to strict discipline, is in effect a universal machine. (Turing 1948: 9.)

The electronic stored-program digital computers for which the universal Turing machine was a blueprint are, each of them, computationally equivalent to a Turing machine with a finite tape, and so they too are, in a sense, models of human beings engaged in computation. Turing chose to emphasise this when explaining these electronic machines in a manner suitable for an audience of uninitiates:

> The idea behind digital computers may be explained by saying that these machines are intended to carry out any operations which could be done by a human computer. (Turing 1950: 436).

He makes the point a little more precisely in the technical document containing his preliminary design for the Automatic Computing Engine or ACE. (The ACE was an electronic stored-program computer built at the National Physical Laboratory, London. A pilot version first ran in 1950 and at the time was the fastest computer in the world. The commercial model was called the DEUCE.)

> The class of problems capable of solution by the machine [the ACE] can be defined fairly specifically. They are [a subset of] those problems which can be solved by human clerical labour, working to fixed rules, and without understanding. (Turing 1946: 38-9.)

(Turing went on to characterise the subset in terms of the amount of paper and time available to the human clerk.) It was presumably because he considered the point under discussion to be essential for

understanding the nature of the new electronic machines that he chose to begin the *Programmers' Handbook for the Manchester Computer* with this explanation:

> Electronic computers are intended to carry out any definite rule of thumb process which could have been done by a human operator working in a disciplined but unintelligent manner. (Turing 1951: 1.)

It was not some deficiency of imagination that led Turing to model his computing machines on what could be achieved by a human computer. The purpose for which the Turing machine was invented demanded it. The Entscheidungsproblem is the problem of finding a *humanly executable* procedure of a certain sort, and Turing's aim was precisely to show that there is no such procedure in the case of predicate logic. He proved that no Turing machine can compute the values of the function D that I described earlier, and he argued that his model of human computation is sufficiently general, in the sense that there are no intuitively computable (i.e. effectively calculable) functions that Turing machines are incapable of computing.

The latter claim is, of course, Turing's thesis. Here are two additional formulations of the thesis, from his paper of 1936.

> [T]he "computable numbers" [the numbers whose decimal representations can be generated progressively by a Turing machine] include all numbers which would naturally be regarded as computable. (Turing 1936: 249.)

> It is my contention that these operations [the primitive operations of a Turing machine] include all those which are used in the computation of a number. (Turing 1936: 232.)

(As Turing explains: "Although the subject of this paper is ostensibly the computable *numbers*, it is almost equally easy to define and investigate computable functions ... I have chosen the computable numbers for explicit treatment as involving the least cumbrous technique" (1936: 230).)

To understand these assertions as Turing intended them it is essential to keep in mind that when he uses the words 'computer', 'computable' and 'computation' he employs them not in their modern sense as pertaining to machines but as pertaining to human calculators. Many passages make this obvious.

> Computers always spend just as long in writing numbers down and deciding what to do next as they do in actual multiplications, and it is just the same with ACE ... [T]he ACE will do the work of about 10,000 computers ... Computers will still be employed on small calculations ... (Turing 1947: 116, 120.)

Thus when Turing maintains that every number or function that 'would naturally be regarded as computable' can be calculated by a Turing machine he is asserting not thesis M but a thesis concerning the extent of the effectively calculable numbers and functions. Similarly, when Church writes (in a review

of Post (1936)):

> To define effectiveness as computability by an arbitrary machine, subject to restrictions of finiteness, would seem to be an adequate representation of the ordinary notion (Church 1937b: 43),

he is to be understood not as entertaining some form of thesis M but as endorsing the identification of the effectively calculable functions with those functions that can be calculated by an arbitrary machine whose principles of operation are such as to mimic the actions of a human computer. (There is much that is ‘arbitrary’ about the machines described (independently, in the same year) by Turing and Post, for example the one-dimensional arrangement of the squares of the tape (or in Post’s case, of the ‘boxes’), the absence of a system of addresses for squares of the tape, the choice between a two-way and a one-way infinite tape, and, in Post’s case, the restriction that a square admit of only two possible conditions, blank or marked by a single vertical stroke.)

It is equally important to note that when Turing uses the word ‘machine’ he often means not machine-in-general but, as we would now say, Turing machine. At one point he explicitly draws attention to this idiosyncratic usage:

> The expression "machine process" of course means one which could be carried out by the type of machine I was considering [in Turing 1936]. (Turing 1947: 107).

Thus when, a few pages later, he asserts that "machine processes and rule of thumb processes are synonymous" (1947: 112), he is to be understood as advancing the Church-Turing thesis (and its converse), not a version of thesis M. Unless this idiosyncratic usage is borne in mind, misunderstanding is certain to ensue. Especially liable to mislead are statements like the following, which a casual reader, unaware of Turing’s idiosyncratic usage, might easily mistake for a formulation of thesis M:

> The importance of the universal machine is clear. We do not need to have an infinity of different machines doing different jobs. A single one will suffice. The engineering problem of producing various machines for various jobs is replaced by the office work of "programming" the universal machine to do these jobs. (Turing 1948: 7.)

In context it is perfectly clear that these remarks concern machines equivalent to Turing machines (the passage is embedded in a discussion of LCMs).

Whether or not Turing would, if queried, have assented to thesis M is unknown. There is certainly no textual evidence in favour of the ubiquitous belief that he did so assent.

Alan M. Turing

Alan Turing (1912-1954) never described himself as a philosopher, but his 1950 paper "Computing Machinery and Intelligence" is one of the most frequently cited in modern philosophical literature. It gave a fresh approach to the traditional mind-body problem, by relating it to the mathematical concept of computability he himself had introduced in his 1936-7 paper "On computable numbers, with an application to the Entscheidungproblem." His work can be regarded as the foundation of computer science and of the artificial intelligence program.

---

1. Outline of Life

Alan Turing's short and extraordinary life has attracted wide interest. It has inspired his mother's memoir (E. S. Turing 1959), a detailed biography (Hodges 1983), a play and television film (Whitemore 1986), and various other works of fiction and art.

There are many reasons for this interest, but one is that in every sphere of his life and work he made unexpected connections between apparently unrelated areas. His central contribution to science and philosophy came through his treating the subject of symbolic logic as a new branch of applied mathematics, giving it a physical and engineering content. Unwilling or unable to remain within any

standard role or department of thought, Alan Turing continued a life full of incongruity. Though a shy, boyish, man, he had a pivotal role in world history through his role in Second World War cryptology. Though the founder of the dominant technology of the twentieth century, he variously impressed, charmed or disturbed people with his unworldly innocence and his dislike of moral or intellectual compromise.

Alan Mathison Turing was born in London, 23 June 1912, to upper-middle-class British parents. His schooling was of a traditional kind, dominated by the British imperial system, but from earliest life his fascination with the scientific impulse -- expressed by him as finding the ‘commonest in nature’ -- found him at odds with authority. His scepticism, and disrespect for worldly values, were never tamed and became ever more confidently eccentric. His moody humour swung between gloom and vivacity. His life was also notable as that of a gay man with strong emotions and a growing insistence on his identity.

His first true home was at King’s College, Cambridge University, noted for its progressive intellectual life centred on J. M. Keynes. Turing studied mathematics with increasing distinction and was elected a Fellow of the college in 1935. This appointment was followed by a remarkable and sudden début in an area where he was an unknown figure: that of mathematical logic. The paper "On Computable Numbers..." (Turing 1936-7) was his first and perhaps greatest triumph. It gave a definition of computation and an absolute limitation on what computation could achieve, which makes it the founding work of modern computer science. It led him to Princeton for more advanced work in logic and other branches of mathematics. He had the opportunity to remain in the United States, but chose to return to Britain in 1938, and was immediately recruited for the British communications war.

From 1939 to 1945 Turing was almost totally engaged in the mastery of the German enciphering machine, Enigma, and other cryptological investigations at now-famous Bletchley Park, the British government’s wartime communications headquarters. Turing made a unique logical contribution to the decryption of the Enigma and became the chief scientific figure, with a particular responsibility for reading the U-boat communications. As such he became a top-level figure in Anglo-American liaison, and also gained exposure to the most advanced electronic technology of the day.

Combining his ideas from mathematical logic, his experience in cryptology, and some practical electronic knowledge, his ambition, at the end of the war in Europe, was to create an electronic computer in the full modern sense. His plans, commissioned by the National Physical Laboratory, London, were overshadowed by the more powerfully supported American projects. Turing also laboured under the disadvantage that his wartime achievements remained totally secret. His ideas led the field in 1946, but this was little recognised. Frustrated in his work, he emerged as a powerful marathon runner, and almost qualified for the British team in the 1948 Olympic games.

Turing’s motivations were scientific rather than industrial or commercial, and he soon returned to the theoretical limitations of computation, this time focussing on the comparison of the power of computation and the power of the human brain. His contention was that the computer, when properly programmed, could rival the brain. It founded the ‘Artifical Intelligence’ program of coming decades.

In 1948 he moved to Manchester University, where he partly fulfilled the expectations placed upon him to plan software for the pioneer computer development there, but still remained a free-ranging thinker. It was here that his famous 1950 paper, "Computing Machinery and Intelligence," (Turing 1950b) was written. In 1951 he was elected a Fellow of the Royal Society for his 1936 achievement, yet at the same time he was striking into entirely new territory with a mathematical theory of biological morphogenesis (Turing 1952).

This work was interrupted by Alan Turing’s arrest in February 1952 for his sexual affair with a young Manchester man, and he was obliged, to escape imprisonment, to undergo the injection of oestrogen intended to negate his sexual drive. He was disqualified from continuing secret cryptological work. His general libertarian attitude was enhanced rather than suppressed by the criminal trial, and his intellectual individuality also remained as lively as ever. While remaining formally a Reader in the Theory of Computing, he not only embarked on more ambitious applications of his biological theory, but advanced new ideas for fundamental physics.

For this reason his death, on 7 June 1954, at his home in Wilmslow, Cheshire, came as a general surprise. In hindsight it is obvious that Turing’s unique status in Anglo-American secret communication work meant that there were pressures on him of which his contemporaries were unaware; there was certainly another ‘security’ conflict with government in 1953 (Hodges 1983, p. 483). Some commentators, e.g. Dawson (1985), have argued that assassination should not be ruled out. But he had spoken of suicide, and his death, which was by cyanide poisoning, was most likely by his own hand, contrived so as to allow those who wished to do so to believe it a result of his penchant for chemistry experiments. The symbolism of its dramatic element -- a partly eaten apple -- has continued to haunt the intellectual Eden from which Alan Turing was expelled.

2. The Turing Machine and Computability

Alan Turing drew much between 1928 and 1933 from the work of the mathematical physicist and populariser A. S. Eddington, from J. von Neumann’s account of the foundations of quantum mechanics, and then from Bertrand Russell’s mathematical logic. Meanwhile, his lasting fascination with the problems of mind and matter was heightened by emotional elements in his own life (Hodges 1983, p. 63). In 1934 he graduated with an outstanding degree in mathematics from Cambridge University, followed by a successful dissertation in probability theory which won him a Fellowship of King’s College, Cambridge, in 1935. This was the background to his learning, also in 1935, of the problem which was to make his name.

It was from the lectures of the topologist M. H. A. (Max) Newman in that year that he learnt of Gödel’s 1931 proof of the formal incompleteness of logical systems rich enough to include arithmetic, and of the outstanding problem in the foundations of mathematics as posed by Hilbert: the "Entscheidungsproblem" (decision problem). Was there a method by which it could be decided, for any given mathematical proposition, whether or not it was provable?

The principal difficulty of this question lay in giving an unassailably correct and general definition of what was meant by such expressions as ‘definite method’ or ‘effective procedure.’ Turing worked on this alone for a year until April 1936; independence and isolation was to be both his strength, in formulating original ideas, and his weakness, when it came to promoting and implementing them.

The word ‘mechanical’ had often been used of the formalist approach lying behind Hilbert’s problem, and Turing seized on the concept of the *machine.*Turing’s solution lay in defining what was soon to be named the *Turing machine.* With this he defined the concept of ‘the mechanical’ in terms of simple atomic operations. The Turing machine formalism was modelled on the teleprinter, slightly enlarged in scope to allow a paper tape that could move in both directions and a ‘head’ that could read, erase and print new symbols, rather than only read and punch permanent holes.

The Turing machine is ‘theoretical,’ in the sense that it is not intended actually to be engineered (there being no point in doing so), although it is essential that its atomic components (the paper tape, movement to left and right, testing for the presence of a symbol) are such as *could* actually be implemented. The whole point of the formalism is to reduce the concept of ‘method’ to simple operations that can unquestionably be ‘effected.’

Nevertheless Turing’s purpose was to embody the most general mechanical process as carried out by a *human being.* His analysis began not with any existing computing machines, but with the picture of a child’s exercise book marked off in squares. From the beginning, the Turing machine concept aimed to capture what the *human mind* can do when carrying out a procedure.

In speaking of ‘the’ Turing machine it should be made clear that there are *infinitely many* Turing machines, each corresponding to a different method or procedure, by virtue of having a different ‘table of behaviour.’ Nowadays it is almost impossible to avoid imagery which did not exist in 1936: that of the computer. In modern terms, the ‘table of behaviour’ of a Turing machine is equivalent to a computer program.

If a Turing machine corresponds to a computer program, what is the analogy of the computer? It is what Turing described as a *universal* machine (Turing 1936-7, p. 241). Again, there are *infinitely many* universal Turing machines, forming a subset of Turing machines; they are those machines with ‘tables of behaviour’ complex enough to read the tables of other Turing machines, and then do what those machines would have done. If this seems strange, note the modern parallel that any computer can be simulated by software on another computer. The way that tables can read and simulate the effect of other tables is crucial to Turing’s theory, going far beyond Babbage’s ideas of a hundred years earlier. It also shows why Turing’s ideas go to the heart of the modern computer, in which it is essential that programs are themselves a form of data which can be manipulated by other programs. But the reader must always remember that in 1936 there were no such computers; indeed the modern computer arose *out of* the formulation of ‘behaving mechanically’ that Turing found in this work.

Turing’s machine formulation allowed the precise definition of the *computable:* namely, as what can be done by a Turing machine acting alone. More exactly, computable operations are those which can be

effected by what Turing called *automatic* machines. The crucial point here is that the action of an automatic Turing machine is totally determined by its ‘table of behaviour’. (Turing also allowed for ‘choice machines’ which call for human inputs, rather than being totally determined.) Turing then proposed that this definition of ‘computable’ captured precisely what was intended by such words as ‘definite method, procedure, mechanical process’ in stating the *Entscheidungsproblem.*

In applying his machine concept to the *Entscheidungsproblem,* Turing took the step of defining *computable numbers.* These are those real numbers, considered as infinite decimals, say, which it is possible for a Turing machine, starting with an empty tape, to print out. For example, the Turing machine which simply prints the digit 1 and moves to the right, then repeats that action for ever, can thereby compute the number .1111111... A more complicated Turing machine can compute the infinite decimal expansion of π.

Turing machines, like computer programs, are countable; indeed they can be ordered in a complete list by a kind of alphabetical ordering of their ‘tables of behaviour’. Turing did this by encoding the tables into ‘description numbers’ which can then be ordered in magnitude. Amongst this list, a subset of them (those with ‘satisfactory’ description numbers) are the machines which have the effect of printing out infinite decimals. It is readily shown, using a ‘diagonal’ argument first used by Cantor and familiar from the discoveries of Russell and Gödel, that there can be no Turing machine with the property of deciding whether a description number is satisfactory or not. The argument can be presented as follows. Suppose that such a Turing machine exists. Then it is possible to construct a new Turing machine which works out in turn the Nth digit from the Nth machine possessing a satisfactory description number. This new machine then prints an Nth digit differing from that digit. As the machine proceeds, it prints out an infinite decimal, and therefore has a ‘satisfactory’ description number. Yet this number must by construction differ from the outputs of every Turing machine with a satisfactory description number. This is a contradiction, so the hypothesis must be false (Turing 1936-7, p. 246). From this, Turing was able to answer Hilbert’s *Entscheidungsproblem* in the negative: there can be no such general method.

Turing’s proof can be recast in many ways, but the core idea depends on the *self-reference* involved in a machine operating on symbols, which is itself described by symbols and so can operate on its own description. Indeed, the self-referential aspect of the theory can be highlighted by a different form of the proof, which Turing preferred (Turing 1936-7, p. 247). Suppose that such a machine for deciding satisfactoriness does exist; then apply it to its own description number. A contradiction can readily be obtained. However, the ‘diagonal’ method has the advantage of bringing out the following: that a real number may be *defined* unambiguously, yet be *uncomputable.* It is a non-trivial discovery that whereas some infinite decimals (e.g. π) may be encapsulated in a finite table, other infinite decimals (in fact, almost all) cannot. Likewise there are decision problems such as ‘is this number prime?’ in which infinitely many answers are wrapped up in a finite recipe, while there are others (again, almost all) which are not, and must be regarded as requiring infinitely many different methods. ‘Is this a provable proposition?’ belongs to the latter category.

This is what Turing established, and into the bargain the remarkable fact that anything that *is* computable can in fact be computed by *one* machine, a universal Turing machine.

It was vital to Turing's work that he justified the definition by showing that it encompassed the most general idea of 'method'. For if it did not, the *Entscheidungproblem* remained open: there might be some more powerful type of method than was encompassed by Turing computability. One justification lay in showing that the definition included many processes a mathematician would consider to be natural in computation (Turing 1936-7, p. 254). Another argument involved a human calculator following written instruction notes. (Turing 1936-7, p. 253). But in a bolder argument, the one he placed first, he considered an 'intuitive' argument appealing to the *states of mind* of a human computer. (Turing 1936-7, p. 249). The entry of 'mind' into his argument was highly significant, but at this stage it was only a mind following a rule.

To summarise: Turing found, and justified on very general and far-reaching grounds, a precise mathematical formulation of the conception of a general process or method. His work, as presented to Newman in April 1936, argued that his formulation of 'computability' encompassed 'the possible processes which can be carried out in computing a number.' (Turing 1936-7, p. 232). This opened up new fields of discovery both in practical computation, and in the discussion of human mental processes. However, although Turing had worked as what Newman called 'a confirmed solitary' (Hodges 1983, p 113), he soon learned that he was not alone in what Gandy (1988) has called 'the confluence of ideas in 1936.'

The Princeton logician Alonzo Church had slightly outpaced Turing in finding a satisfactory definition of what he called 'effective calculability.' Church's definition required the logical formalism of the *lambda-calculus.* This meant that from the outset Turing's achievement merged with and superseded the formulation of *Church's Thesis,* namely the assertion that the lambda-calculus formalism correctly embodied the concept of effective process or method. Very rapidly it was shown that the mathematical scope of Turing computability coincided with Church's definition (and also with the scope of the *general recursive functions* defined by Gödel). Turing wrote his own statement (Turing 1939, p. 166) of the conclusions that had been reached in 1938; it is in the Ph.D. thesis that he wrote under Church's supervision, and so this statement is the nearest we have to a joint statement of the 'Church-Turing thesis':

> A function is said to be 'effectively calculable' if its values can be found by some purely mechanical process. Although it is fairly easy to get an intuitive grasp of this idea, it is nevertheless desirable to have some more definite, mathematically expressible definition. Such a definition was first given by Gödel at Princeton in 1934... These functions were described as 'general recursive' by Gödel... Another definition of effective calculability has been given by Church... who identifies it with lambda-definability. The author [i.e. Turing] has recently suggested a definition corresponding more closely to the intuitive idea... It was stated above that 'a function is effectively calculable if its values can be found by a purely mechanical process.' We may take this statement literally, understanding by a purely mechanical process one which could be carried out by a machine. It is possible to give a mathematical description, in a certain normal form, of the structures of these machines. The development of these ideas leads to the author's definition of a computable function, and to

> an identification of computability with effective calculability. It is not difficult, though somewhat laborious, to prove that these three definitions are equivalent.

Church accepted that Turing's definition gave a compelling, intuitive reason for why Church's thesis was true. The recent exposition by Davis (2000) emphasises that Gödel also was convinced by Turing's argument that an absolute concept had been identified (Gödel 1946). The situation has not changed since 1937. (For further comment, see the article on the Church-Turing Thesis.)

Turing himself did little to evangelise his formulation in the world of mathematical logic and early computer science. The textbooks of Davis (1958) and Minsky (1967) did more. Nowadays Turing computability is often reformulated (e.g. in terms of 'register machines'). However, computer simulations (e.g., Turing's World, from Stanford) have brought Turing's original imagery to life.

Turing's work also opened new areas for decidability questions within pure mathematics. From the 1970s, Turing machines also took on new life in the development of *complexity theory,* and as such underpin one of the most important research areas in computer science. This development exemplifies the lasting value of Turing's special quality of giving concrete illustration to abstract concepts.

3. The Logical and the Physical

As put by Gandy (1988), Turing's paper was 'a paradigm of philosophical analysis,' refining a vague notion into a precise definition. But it was more than being an analysis *within* the world of mathematical logic: in Turing's thought the question that constantly recurs both theoretically and practically is the relationship of the logical Turing machine to the physical world.

'Effective' means *doing,* not merely imagining or postulating. At this stage neither Turing nor any other logician made a serious investigation into the physics of such 'doing.' But Turing's image of a teleprinter-like machine does inescapably refer to something that could actually be physically 'done.' His concept is a distillation of the idea that one can only 'do' one simple action, or finite number of simple actions, at a time. How 'physical' a concept is it?

The tape never holds more than a finite number of marked squares at any point in a computation. Thus it can be thought of as being finite, but always capable of further extension as required. Obviously this unbounded extendibility is unphysical, but the definition is still of practical use: it means that anything done on a finite tape, however large, is computable. (Turing himself took such a finitistic approach when explaining the practical relevance of computability in his 1950 paper.) One aspect of Turing's formulation, however, involves absolute finiteness: the table of behaviour of a Turing machine must be finite, since Turing allows only a finite number of 'configurations' of a Turing machine, and only a finite repertoire of symbols which can be marked on the tape. This is essentially equivalent to allowing only computer programs with finite lengths of code.

'Calculable by finite means' was Turing's characterisation of computability, which he justified with the argument that 'the human memory is necessarily limited.' (Turing 1936-7, p. 231). The whole point of his definition lies in encoding infinite potential effects, (e.g. the printing of an infinite decimal) into finite 'tables of behaviour'. There would be no point in allowing machines with infinite 'tables of behaviour'. It is obvious, for instance, that any real number could be printed by such a 'machine', by letting the Nth configuration be 'programmed' to print the Nth digit, for example. Such a 'machine' could likewise store any countable number of statements about all possible mathematical expressions, and so make the *Entscheidungsproblem* trivial.

Church (1937), when reviewing Turing's paper while Turing was in Princeton under his supervision, actually gave a bolder characterisation of the Turing machine as an *arbitrary finite machine.*

> The author [i.e. Turing] proposes as a criterion that an infinite sequence of digits 0 and 1 be "computable" that it shall be possible to devise a computing machine, occupying a finite space and with working parts of finite size, which will write down the sequence to any desired number of terms if allowed to run for a sufficiently long time. As a matter of convenience, certain further restrictions are imposed on the character of the machine, but these are of such a nature as obviously to cause no loss of generality -- in particular, a human calculator, provided with pencil and paper and explicit instructions, can be regarded as a kind of Turing machine.

Church (1940) repeated this characterisation. Turing neither endorsed it nor said anything to contradict it, leaving the general concept of 'machine' itself undefined. The work of Gandy (1980) did more to justify this characterisation, by refining the statement of what is meant by 'a machine.' His results support Church's statement; they also argue strongly for the view that natural attempts to extend the notion of computability lead to trivialisation: if Gandy's conditions on a 'machine' are significantly weakened then every real number becomes calculable (Gandy 1980, p. 130ff.). (For a different interpretation of Church's statement, see the article on the Church-Turing Thesis.)

Turing did not explicitly discuss the question of the *speed* of his elementary actions. It is left implicit in his discussion, by his use of the word 'never,' that it is not possible for infinitely many steps to be performed in a finite time. Others have explored the effect of abandoning this restriction. Davies (2001), for instance, describes a 'machine' with an infinite number of parts, requiring components of arbitrarily small size, running at arbitrarily high speeds. Such a 'machine' could perform uncomputable tasks. Davies emphasises that such a machine cannot be built in our own physical world, but argues that it could be constructed in a universe with different physics. To the extent that it rules out such 'machines', the Church-Turing thesis must have at least some physical content.

True physics is quantum-mechanical, and this implies a different idea of matter and action from Turing's purely classical picture. It is perhaps odd that Turing did not point this out in this period, since he was well versed in quantum physics. Instead, the analysis and practical development of quantum computing was left to the 1980s. Quantum computation, using the evolution of wave-functions rather than classical machine states, is the most important way in which Turing machine model has been challenged. The

standard formulation of quantum computing (Deutsch 1985, following Feynman 1982) does not predict anything beyond computable effects, although within the realm of the computable, quantum computations may be very much more efficient than classical computations. It is possible that a deeper understanding of quantum mechanical physics may further change the picture of what can be physically 'done.'

4. The Uncomputable

Turing turned to the exploration of the *uncomputable* for his Princeton Ph.D. thesis (1938), which then appeared as *Systems of Logic based on Ordinals* (Turing 1939).

It is generally the view, as expressed by Feferman (1988), that this work was a diversion from the main thrust of his work. But from another angle, as expressed in (Hodges 1997), one can see Turing's development as turning naturally from considering the mind when following a rule, to the action of the mind when *not* following a rule. In particular this 1938 work considered the mind when seeing the truth of one of Gödel's true but formally unprovable propositions, and hence going beyond rules based on the axioms of the system. As Turing expressed it (Turing 1939, p. 198), there are 'formulae, seen intuitively to be correct, but which the Gödel theorem shows are unprovable in the original system.' Turing's theory of 'ordinal logics' was an attempt to 'avoid as far as possible the effects of Gödel's theorem' by studying the effect of adding Gödel sentences as new axioms to create stronger and stronger logics. It did not reach a definitive conclusion.

In his investigation, Turing introduced the idea of an 'oracle' capable of performing, as if by magic, an uncomputable operation. Turing's oracle cannot be considered as some 'black box' component of a new class of machines, to be put on a par with the primitive operations of reading single symbols, as has been suggested by (Copeland 1998). An oracle is *infinitely more powerful* than anything a modern computer can do, and nothing like an elementary component of a computer. Turing defined 'oracle-machines' as Turing machines with an additional configuration in which they 'call the oracle' so as to take an uncomputable step. But these oracle-machines are *not purely mechanical.* They are only partially mechanical, like Turing's choice-machines. Indeed the *whole point* of the oracle-machine is to explore the realm of what *cannot* be done by purely mechanical processes. Turing emphasised (Turing 1939, p. 173):

> We shall not go any further into the nature of this oracle apart from saying that it cannot be a machine.

Turing's oracle can be seen simply as a mathematical tool, useful for exploring the mathematics of the uncomputable. The idea of an oracle allows the formulation of questions of *relative* rather than absolute computability. Thus Turing opened new fields of investigation in mathematical logic. However, there is also a possible interpretation in terms of human cognitive capacity. On this interpretation, the oracle is related to the 'intuition' involved in seeing the truth of a Gödel statement. M. H. A. Newman, who introduced Turing to mathematical logic and continued to collaborate with him, wrote in (Newman 1955) that the oracle resembles a mathematician 'having an idea', as opposed to using a mechanical method. However, Turing's oracle cannot actually be *identified* with a human mental faculty. It is too powerful: it

immediately supplies the answer as to whether any given Turing machine is 'satisfactory,' something no human being could do. On the other hand, anyone hoping to see mental 'intuition' captured completely by an oracle, must face the difficulty that Turing showed how his argument for the incompleteness of Turing machines could be applied with equal force to oracle-machines (Turing 1939, p. 173). This point has been emphasised by Penrose (1994, p. 380). Newman's comment might better be taken to refer to the different oracle suggested later on (Turing 1939, p. 200), which has the property of recognising 'ordinal formulae.' One can only safely say that Turing's interest at this time in uncomputable operations appears in the *general setting* of studying the mental 'intuition' of truths which are not established by following mechanical processes (Turing 1939, p. 214ff.).

In Turing's presentation, intuition is in practice present in every part of a mathematician's thought, but when mathematical proof is formalised, intuition has an explicit manifestation in those steps where the mathematician sees the truth of a formally unprovable statement. Turing did not offer any suggestion as to what he considered the brain was physically doing in a moment of such 'intuition'; indeed the word 'brain' did not appear in his writing in this era. This question is of interest because of the views of Penrose (1989, 1990, 1994, 1996) on just this issue: Penrose holds that the ability of the mind to see formally unprovable truths shows that there must be uncomputable physical operations in the brain. It should be noted that there is widespread disagreement about whether the human mind is really seeing the truth of a Gödel sentence; see for instance the discussion in (Penrose 1990) and the reviews following it. However Turing's writing at this period accepted without criticism the concept of intuitive recognition of the truth.

It was also at this period that Turing met Wittgenstein, and there is a full record of their 1939 discussions on the foundations of mathematics in (Diamond 1976). To the disappointment of many, there is no record of any discussions between them, verbal or written, on the problem of Mind.

In 1939 Turing's various energetic investigations were broken off for war work. This did, however, have the positive feature of leading Turing to turn his universal machine into the practical form of the modern digital computer.

5. Building a Universal Machine

When apprised in 1936 of Turing's idea for a universal machine, Turing's contemporary and friend, the economist David Champernowne, reacted by saying that such a thing was impractical; it would need 'the Albert Hall.' If built from relays as then employed in telephone exchanges, that might indeed have been so, and Turing made no attempt at it. However, in 1937 Turing did work with relays on a smaller machine with a special cryptological function (Hodges 1983, p. 138). World history then led Turing to his unique role in the Enigma problem, to his becoming the chief figure in the mechanisation of logical procedures, and to his being introduced to ever faster and more ambitious technology as the war continued.

After 1942, Turing learnt that electronic components offered the speed, storage capacity and logical functions required to be effective as 'tapes' and instruction tables. So from 1945, Turing tried to use

electronics to turn his universal machine into practical reality. Turing rapidly composed a detailed plan for a modern stored-program computer: that is, a computer in which data and instructions are stored and manipulated alike. Turing's ideas led the field, although his report of 1946 postdated von Neumann's more famous EDVAC report (von Neumann 1945). It can however be argued, as does Davis (2000), that von Neumann gained his fundamental insight into the computer through his pre-war familiarity with Turing's logical work. At the time, however, these basic principles were not much discussed. The difficulty of engineering the electronic hardware dominated everything.

It therefore escaped observers that Turing was ahead of von Neumann and everyone else on the future of software, or as he called it, the 'construction of instruction tables.' Turing (1946) foresaw at once:

> Instruction tables will have to be made up by mathematicians with computing experiences and perhaps a certain puzzle-solving ability. There will probably be a great deal of work to be done, for every known process has got to be translated into instruction table form at some stage.
>
> The process of constructing instruction tables should be very fascinating. There need be no real danger of it ever becoming a drudge, for any processes that are quite mechanical may be turned over to the machine itself.

These remarks, reflecting the universality of the computer, and its ability to manipulate its own instructions, correctly described the future trajectory of the computer industry. However, Turing had in mind something greater: 'building a brain.'

6. Building a Brain

The provocative words 'building a brain' from the outset announced the relationship of Turing's technical computer engineering to a philosophy of Mind. Even in 1936, Turing had given an interpretation of computability in terms of 'states of mind'. His war work had shown the astounding power of the computable in mechanising expert human procedures and judgments. From 1941 onwards, Turing had also discussed the mechanisation of chess-playing and other 'intelligent' activities with his colleagues at Bletchley Park (Hodges 1983, p. 213). But more profoundly, it appears that Turing emerged in 1945 with a conviction that computable operations were sufficient to embrace *all* mental functions performed by the brain. As will become clear from the ensuing discussion, the uncomputable 'intuition' of 1938 disappeared from Turing's thought, and was replaced by new ideas all lying within the realm of the computable. This change shows even in the technical prospectus of (Turing 1946), where Turing referred to the possibility of making a machine calculate chess moves, and then continued:

> This ... raises the question 'Can a machine play chess?' It could fairly easily be made to play a rather bad game. It would be bad because chess requires intelligence. We stated ... that the machine should be treated as entirely without intelligence. There are indications however that it is possible to make the machine display intelligence at the risk of its making

> occasional serious mistakes. By following up this aspect the machine could probably be made to play very good chess.

The puzzling reference to 'mistakes' is made clear by a talk Turing gave a year later (Turing 1947), in which the issue of mistakes is linked to the issue of the significance of seeing the truth of formally unprovable statements.

> ...I would say that fair play must be given to the machine. Instead of it giving no answer we could arrange that it gives occasional wrong answers. But the human mathematician would likewise make blunders when trying out new techniques... In other words then, if a machine is expected to be infallible, it cannot also be intelligent. There are several mathematical theorems which say almost exactly that. But these theorems say nothing about how much intelligence may be displayed if a machine makes no pretence at infallibility.

Turing's post-war view was that mathematicians make mistakes, and so do not in fact see the truth infallibly. Once the possibility of mistakes is admitted, Gödel's theorem become irrelevant. Mathematicians and computers alike apply computable processes to the problem of judging the correctness of assertions; both will therefore sometimes err, since seeing the truth is known not to be a computable operation, but there is no reason why the computer need do worse than the mathematician. This argument is still very much alive. For instance, Davis (2000) endorses Turing's view and attacks Penrose (1989, 1990, 1994, 1996) who argues against the significance of human error on the grounds of a Platonist account of mathematics.

Turing also pursued more constructively the question of how computers could be made to perform operations which did not appear to be 'mechanical' (to use common parlance). His guiding principle was that it should be possible to simulate the operation of human brains. In an unpublished report (Turing 1948), Turing explained that the question was that of how to simulate 'initiative' in addition to 'discipline' -- comparable to the need for 'intuition' as well as mechanical ingenuity expressed in his pre-war work. He announced ideas for how to achieve this: he thought 'initiative' could arise from systems where the algorithm applied is not consciously designed, but is arrived at by some other means. Thus, he now seemed to think that the mind when *not* actually following any conscious rule or plan, was nevertheless carrying out some computable process.

He suggested a range of ideas for systems which could be said to modify their own programs. These ideas included nets of logical components ('unorganised machines') whose properties could be 'trained' into a desired function. Thus, as expressed by (Ince 1989), he predicted neural networks. However, Turing's nets did not have the 'layered' structure of the neural networks that were to be developed from the 1950s onwards. By the expression 'genetical or evolutionary search', he also anticipated the 'genetic algorithms' which since the late 1980s have been developed as a less closely structured approach to self-modifying programs. Turing's proposals were not well developed in 1948, and at a time when electronic computers were only barely in operation, could not have been. Fresh attention to them has been drawn by Copeland and Proudfoot (1996), and they have now have been tried out (Teuscher 2001).

It is important to note that Turing identified his prototype neural networks and genetic algorithms as *computable*. This has to be emphasised since the word ‘nonalgorithmic’ is often now confusingly employed for computer operations that are not explicitly planned. Indeed, his ambition was explicit: he himself wanted to implement them as programs on a computer. Using the term Universal Practical Computing Machine for what is now called a digital computer, he wrote in (Turing 1948):

> It should be easy to make a model of any particular machine that one wishes to work on within such a UPCM instead of having to work with a paper machine as at present. If one also decided on quite definite ‘teaching policies’ these could also be programmed into the machine. One would then allow the whole system to run for an appreciable period, and then break in as a kind of ‘inspector of schools’ and see what progress had been made. One might also be able to make some progress with unorganised machines...

The upshot of this line of thought is that all mental operations are *computable* and hence realisable on a universal machine: the computer. Turing advanced this view with increasing confidence in the late 1940s, perfectly aware that it represented what he enjoyed calling ‘heresy’ to the believers in minds or souls beyond material description.

Turing was not a mechanical thinker, or a stickler for convention; far from it. Of all people, he knew the nature of originality and individual independence. Even in tackling the U-boat Enigma problem, for instance, he declared that he did so because no-one else was looking at it and he could have it to himself. Far from being trained or organised into this problem, he took it on despite the prevailing wisdom in 1939 that it was too difficult to attempt. His arrival at a thesis of ‘machine intelligence’ was not the outcome of some dull or restricted mentality, or a lack of appreciation of individual human creativity.

7. Machine Intelligence

Turing relished the paradox of ‘Machine Intelligence’: an apparent contradiction in terms. It is likely that he was already savouring this theme in 1941, when he read a theological book by the author Dorothy Sayers (Sayers 1941). In (Turing 1948) he quoted from this work to illustrate his full awareness that in common parlance ‘mechanical’ was used to to mean ‘devoid of intelligence.’ Giving a date which no doubt had his highly sophisticated Enigma-breaking machines secretly in mind, he wrote that ‘up to 1940’ only very limited machinery had been used, and this ‘encouraged the belief that machinery was necessarily limited to extremely straightforward, possibly even to repetitious, jobs.’ His object was to dispel these connotations.

In 1950, Turing wrote on the first page of his Manual for users of the Manchester University computer (Turing 1950a):

> Electronic computers are intended to carry out any definite rule of thumb process which could have been done by a human operator working in a disciplined but unintelligent manner.

This is, of course, just the 1936 universal Turing machine, now in electronic form. On the other hand, he also wrote in the more famous paper of that year (Turing 1950b, p. 460)

> We may hope that machines will eventually compete with men in all purely intellectual fields.

How could the *intelligent* arise from operations which were themselves totally *routine and mindless* -- 'entirely without intelligence'? This is the core of the problem Turing faced, and the same problem faces Artificial Intelligence research today. Turing's underlying argument was that the human brain must somehow be organised for intelligence, and that the organisation of the brain must be realisable as a finite discrete-state machine. The implications of this view were exposed to a wider circle in his famous paper, "Computing Machinery and Intelligence," which appeared in *Mind* in October 1950.

The appearance of this paper, Turing's first foray into a journal of philosophy, was stimulated by his discussions at Manchester University with Michael Polanyi. It also reflects the general sympathy of Gilbert Ryle, editor of *Mind*, with Turing's point of view.

Turing's 1950 paper was meant for a wide readership and should be read in its original; it has often been reprinted. Not surprisingly, the paper has attracted many critiques. Not all commentators note the careful explication of computability which opens the paper, with an emphasis on the concept of the universal machine. This explains why if mental function can be achieved by any finite discrete state machine, then the same effect can be achieved by programming a computer (Turing 1950b, p. 442). (Note, however, that Turing makes no claim that the nervous system should resemble a digital computer in its structure.) Turing's treatment has a severely finitistic flavour: his argument is that the relevant action of the brain is not only computable, but realisable as a totally finite machine, i.e. as a Turing machine that does not use any 'tape' at all. In his account, the full range of computable functions, defined in terms of Turing machines that use an infinite tape, only appears as being of 'special theoretical interest.' (Of uncomputable functions there is, *a fortiori,* no mention.) Turing uses the finiteness of the nervous system to give an estimate of about 10^9 bits of storage required for a limited simulation of intelligence (Turing 1950b, p. 455).

The wit and drama of Turing's 'imitation game' has attracted more fame than his careful groundwork. Turing's argument was designed to bypass discussions of the nature of thought, mind, and consciousness, and to give a criterion in terms of external observation alone. His justification for this was that one only judges that other human beings are thinking by external observation, and he applied a principle of 'fair play for machines' to argue that the same should hold for machine intelligence. He dramatised this viewpoint by a thought-experiment (which nowadays can readily be tried out). A human being and a programmed computer compete to convince an impartial judge, using textual messsages alone, as to which is the human being. If the computer wins, it must be credited with intelligence.

Turing introduced his 'game' confusingly with a poor analogy: a party game in which a man pretends to

be a woman. His loose wording (Turing 1950b, p. 434) has led some writers wrongly to suppose that Turing proposed an ‘imitation game’ in which a machine has to imitate a man imitating a woman. Others, like Lassègue (1998), place much weight on this game of gender pretence and its real or imaginary connotations. In fact, the whole point of the ‘test’ setting, with its remote text-message link, was to *separate* intelligence from other human faculties and properties. But it may fairly be said that this confusion reflects Turing’s richly ambitious concept of what is involved in human ‘intelligence’. It might also be said to illustrate his own human intelligence, in particular a delight in the Wildean reversal of roles, perhaps reflecting, as in Wilde, his homosexual identity. His friends knew an Alan Turing in whom intelligence, humour and sex were often intermingled.

Turing was in fact sensitive to the difficulty of separating ‘intelligence’ from other aspects of human senses and actions; he described ideas for robots with sensory attachments and raised questions as to whether they might enjoy strawberries and cream or feel racial kinship. In contrast, he paid scant attention to the questions of authenticity and deception implicit in his test, essentially because he wished to by-pass questions about the reality of consciousness. A subtle aspect of one of his imagined ‘intelligent’ conversations (Turing 1950b, p. 434) is where the computer imitates human intelligence by giving the *wrong answer* to a simple arithmetic problem. But in Turing’s setting we are not supposed to ask whether the computer ‘consciously’ deceives by giving the impression of innumerate humanity, nor why it should wish to do so. There is a certain lack of seriousness in this approach. Turing took on a second-rank target in countering the published views of the brain surgeon G. Jefferson, as regards the objectivity of consciousness. Wittgenstein’s views on Mind would have made a more serious point of departure.

Turing’s imitation principle perhaps also assumes (like ‘intelligence tests’ of that epoch) too much of a shared language and culture for his imagined interrogations. Neither does it address the possibility that there may be kinds of thought, by animals or extra-terrestrial intelligences, which are not amenable to communication.

A more positive feature of the paper lies in its constructive program for research, culminating in Turing’s ideas for ‘learning machines’ and educating ‘child’ machines (Turing 1950b, p. 454). It is generally thought (e.g. in Dreyfus and Dreyfus 1990) that there was always an antagonism between programming and the ‘connectionist’ approach of neural networks. But Turing never expressed such a dichotomy, writing that both approaches should be tried. Donald Michie, the British AI research pioneer profoundly influenced by early discussions with Turing, has called this suggestion ‘Alan Turing’s Buried Treasure’, in an allusion to a bizarre wartime episode in which Michie was himself involved (Hodges 1983, p. 345). The question is still highly pertinent.

It is also a commonly expressed view that Artifical Intelligence ideas only occurred to pioneers in the 1950s *after* the success of computers in large arithmetical calculations. It is hard to see why Turing’s work, which was rooted from the outset in the question of mechanising Mind, has been so much overlooked. But through his failure to publish and promote work such as that in (Turing 1948) he largely lost recognition and influence.

It is also curious that Turing’s best-known paper should appear in a journal of philosophy, for it may well

be said that Turing, always committed to materialist explanation, was not really a philosopher at all. Turing was a mathematician, and what he had to offer philosophy lay in illuminating its field with what had been discovered in mathematics and physics. In the 1950 paper this was surprisingly cursory, apart from his groundwork on the concept of computability. His emphasis on the sufficiency of the computable to explain the action of the mind was stated more as a hypothesis, even a manifesto, than argued in detail. Of his hypothesis he wrote (Turing 1950b, p. 442):

> ...I believe that at the end of the century the use of words and general educated opinion will have altered so much that one will be able to speak of machines thinking without expecting to be contradicted. I believe further that no useful purpose is served by concealing these beliefs. The popular view that scientists proceed inexorably from established fact to established fact, never being influenced by any unproved conjecture, is quite mistaken. Provided it is made clear which are proved facts and which are conjecture, no harm can result. Conjectures are of great importance since they suggest useful lines of research.

Penrose (1994, p.21), probing into Turing's conjecture, has presented it as 'Turing's thesis' thus:

> It seems likely that he viewed physical action in general -- which would include the action of a human brain -- to be always reducible to some kind of Turing-machine action.

The statement that all physical action is in effect computable goes beyond Turing's explicit words, but is a fair characterisation of the implicit assumptions behind the 1950 paper. Turing's consideration of 'The Argument from Continuity in the Nervous System,' in particular, simply asserts that the physical system of the brain can be approximated as closely as is desired by a computer program (Turing 1950b, p. 451). Certainly there is nothing in Turing's work in the 1945-50 period to contradict Penrose's interpretation. The more technical precursor papers (Turing 1947, 1948) include wide-ranging comments on physical processes, but make no reference to the possibility of physical effects being uncomputable.

In particular, a section of (Turing 1948) is devoted to a general classification of 'machines.' The period between 1937 and 1948 had given Turing much more experience of actual machinery than he had in 1936, and his post-war remarks reflected this in a down-to-earth manner. Turing distinguished 'controlling' from 'active' machinery, the latter being illustrated by 'a bulldozer'. Naturally it is the former -- in modern terms 'information-based machinery' -- with which Turing's analysis is concerned. It is noteworthy that in 1948 as in 1936, despite his knowledge of physics, Turing made no mention of how quantum mechanics might affect the concept of 'controlling'. His concept of 'controlling' remained entirely within the classical framework of the Turing machine (which he called a Logical Computing Machine in this paper.)

The same section of (Turing 1948) also drew the distinction between *discrete* and *continuous* machinery, illustrating the latter with 'the telephone' as a continuous, controlling machine. He made light of the difficulty of reducing continuous physics to the discrete model of the Turing machine, and though citing 'the brain' as a continuous machine, stated that it could probably be treated as if discrete. He gave no indication that physical continuity threatened the paramount role of computability. In fact, his thrust in

(Turing 1947) was to promote the digital computer as *more powerful* than analog machines such as the differential analyser. When he discussed this comparison, he gave the following informal version of the Church-Turing thesis:

> One of my conclusions was that the idea of a ‘rule of thumb’ process and a ‘machine process’ were synonymous. The expression ‘machine process’ of course means one which could be carried out by the type of machine I was considering [i.e. Turing machines]

Turing gave no hint that the discreteness of the Turing machine consituted a real limitation, or that the non-discrete processes of analog machines might be of any deep significance.

Turing also introduced the idea of ‘random elements’ but his examples (using the digits of π) showed that he considered *pseudo-random* sequences (i.e. computable sequences with suitable ‘random’ properties) quite adequate for his discussion. He made no suggestion that randomness implied something uncomputable, and indeed gave no definition of the term ‘random’. This is perhaps surprising in view of the fact that his work in pure mathematics, logic and cryptography all gave him considerable motivation to approach this question at a serious level.

8. Unfinished Work

From 1950 Turing worked on a new mathematical theory of morphogenesis, based on showing the consequences of non-linear equations for chemical reaction and diffusion (Turing 1952). He was a pioneer in using a computer for such work. Some writers have referred to this theory as founding Artificial Life (A-life), but this is a misleading description, apt only to the extent that the theory was intended, as Turing saw it, to counter the Argument from Design. A-life since the 1980s has concerned itself with using computers to explore the logical consequences of evolutionary theory without worrying about specific physiological forms. Morphogenesis is complementary, being concerned to show which physiological pathways are feasible for evolution to exploit. Turing’s work was developed by others in the 1970s and is now regarded as central to this field.

It may well be that Turing’s interest in morphogenesis went back to a primordial childhood wonder at the appearance of plants and flowers. But in another late development, Turing went back to other stimuli of his youth. For in 1951 Turing did consider the problem, hitherto avoided, of setting computability in the context of quantum-mechanical physics. In a BBC radio talk of that year (Turing 1951) he discussed the basic groundwork of his 1950 paper, but this time dealing rather less certainly with the argument from Gödel’s theorem, and this time also referring to the quantum-mechanical physics underlying the brain. Turing described the universal machine property, applying it to the brain, but said that its applicability required that the machine whose behaviour is to be imitated

> ...should be of the sort whose behaviour is in principle predictable by calculation. We certainly do not know how any such calculation should be done, and it was even argued by Sir Arthur Eddington that on account of the indeterminacy principle in quantum mechanics

> no such prediction is even theoretically possible.

Copeland (1999) has rightly drawn attention to this sentence in his preface to his edition of the 1951 talk. However, Copeland's critical context suggests some connection with Turing's 'oracle.' There is is in fact no mention of oracles here (nor anywhere in Turing's post-war discussion of mind and machine.) Turing here is discussing the possiblility that, when seen as as a *quantum-mechanical machine* rather than a classical machine, the Turing machine model is inadequate. The correct connection to draw is not with Turing's 1938 work on ordinal logics, but with his knowledge of quantum mechanics from Eddington and von Neumann in his youth. Indeed, in an early speculation, influenced by Eddington, Turing had suggested that quantum mechanical physics could yield the basis of free-will (Hodges 1983, p. 63). Von Neumann's axioms of quantum mechanics involve two processes: unitary evolution of the wave function, which is predictable, and the measurement or reduction operation, which introduces unpredictability. Turing's reference to unpredictability must therefore refer to the reduction process. The essential difficulty is that still to this day there is no agreed or compelling theory of when or how reduction actually occurs. (It should be noted that 'quantum computing,' in the standard modern sense, is based on the predictability of the unitary evolution, and does not, as yet, go into the question of how reduction occurs.) It seems that this single sentence indicates the beginning of a new field of investigation for Turing, this time into the foundations of quantum mechanics. In 1953 Turing wrote to his friend and student Robin Gandy that he was 'trying to invent a new Quantum Mechanics but it won't really work.'

At Turing's death in June 1954, Gandy reported in a letter to Newman on what he knew of Turing's current work (Gandy 1954). He wrote of Turing having discussed a problem in understanding the reduction process, in the form of

> ...'the Turing Paradox'; it is easy to show using standard theory that if a system start in an eigenstate of some observable, and measurements are made of that observable N times a second, then, even if the state is not a stationary one, the probability that the system will be in the same state after, say, 1 second, tends to one as N tends to infinity; i.e. that continual observation will prevent motion. Alan and I tackled one or two theoretical physicists with this, and they rather pooh-poohed it by saying that continual observation is not possible. But there is nothing in the standard books (eg Dirac's) to this effect, so that at least the paradox shows up an inadequacy of Quantum Theory as usually presented.

Turing's investigations take on added significance in view of the assertion of Penrose (1989, 1990, 1994, 1996) that the reduction process must involve something uncomputable. Probably Turing was aiming at the opposite idea, of finding a theory of the reduction process that would be predictive and computable, and so plug the gap in his hypothesis that the action of the brain is computable. However Turing and Penrose are alike in seeing this as an important question affecting the assumption that all mental action is computable; in this they both differ from the mainstream view in which the question is accorded little significance.

Alan Turing's last postcards to Robin Gandy, in March 1954, headed 'Messages from the Unseen World' in allusion to Eddington, hinted at new ideas in the fundamental physics of relativity and particle physics

(Hodges 1983, p. 512). They illustrate the wealth of ideas with which he was concerned at that last point in his life, but which apart from these hints are entirely lost.

9. Alan Turing: the Unknown Mind

It is a pity that Turing did not write more about his ethical philosophy and world outlook. As a student he was an admirer of Bernard Shaw's plays of ideas, and to friends would openly voice both the hilarities and frustrations of his many difficult situations. Yet the nearest he came to serious personal writing, apart from occasional comments in private letters, was in penning a short story about his 1952 crisis (Hodges 1983, p. 448). His last two years were particularly full of Shavian drama and Wildean irony. In one letter (to his friend Norman Routledge; the letter is now in the Turing Archive at King's College, Cambridge) he wrote:

> Turing believes machines think
> Turing lies with men
> Therefore machines do not think

The syllogistic allusion to Socrates is unmistakeable, and his demise, with cyanide rather than hemlock, may have signalled something similar. A parallel figure in World War II, Robert Oppenheimer, suffered the loss of his reputation during the same week that Turing died. Both combined the purest scientific work and the most effective application of science in war. Alan Turing was even more directly on the receiving end of science, when his sexual mind was treated as a machine, against his protesting consciousness and will. But amidst all this human drama, he left little to say about what he really thought of himself and his relationship to the world of human events.

Alan Turing did not fit easily with any of the intellectual movements of his time, aesthetic, technocratic or marxist. In the 1950s, commentators struggled to find discreet words to categorise him: as 'a scientific Shelley,' as possessing great 'moral integrity'. But until the 1970s the reality of his life was unmentionable. He is still hard to place within twentieth-century thought. He exalted the science that existentialists held to have had robbed life of meaning. The most original figure, the most insistent on personal freedom, he held originality and will to be susceptible to mechanisation. The mind of Alan Turing remains an enigma.

Turing Machine

A Turing machine is an abstract representation of a computing device. It consists of a read/write head that scans a (possibly infinite) one-dimensional (bi-directional) tape divided into squares, each of which is inscribed with a 0 or 1. Computation begins with the machine, in a given "state", scanning a square. It erases what it finds there, prints a 0 or 1, moves to an adjacent square, and goes into a new state. This behavior is completely determined by three parameters: (1) the state the machine is in, (2) the number on the square it is scanning, and (3) a table of instructions. The table of instructions specifies, for each state and binary input, what the machine should write, which direction it should move in, and which state it should go into. (E.g., "If in State 1 scanning a 0: print 1, move left, and go into State 3".) The table can list only finitely many states, each of which becomes implicitly defined by the role it plays in the table of instructions. These states are often referred to as the "functional states" of the machine.

A Turing machine, therefore, is more like a computer program (software) than a computer (hardware). Any given Turing machine can be realized or implemented on an infinite number of different physical computing devices. Computer scientists and logicians have shown that Turing machines -- given enough time and tape -- can compute any function that any conventional digital computers can compute. Also, a ‘probabilistic automaton’ can be defined as a Turing machine in which the transition from input and state to output and state takes place with a certain probability (E.g. "If in State 1 scanning a 0: (a) there is a 60% probability that the machine will print 1, move left, and go into State 3, and (b) there is a 40% probability that the machine will print 0, move left, and go into State 2".)

History

Turing machines were first proposed by Alan Turing, in an attempt to give a mathematically precise definition of "algorithm" or "mechanical procedure". Early work by Turing and Alonzo Church spawned the branch of mathematical logic now known as recursive function theory.

Later Developments

The concept of a Turing machine has played an important role in the recent philosophy of mind. The suggestion has been made that mental states just are functional states of a probabilistic automaton, in which binary inputs and outputs have been replaced by sensory inputs and motor outputs. This idea underlies the theory of mind known as "machine functionalism".

The Modern History of Computing

Historically, computers were human clerks who calculated in accordance with effective methods. These human computers did the sorts of calculation nowadays carried out by electronic computers, and many thousands of them were employed in commerce, government, and research establishments. The term *computing machine*, used increasingly from the 1920s, refers to any machine that does the work of a human computer, i.e. any machine that calculates in accordance with effective methods. During the late 1940s and early 1950s, with the advent of electronic computing machines, the phrase 'computing machine' gradually gave way simply to 'computer', initially usually with the prefix 'electronic' or 'digital'. This entry surveys the history of these machines.

Babbage

Charles Babbage was Lucasian Professor of Mathematics at Cambridge University from 1828 to 1839 (a post formerly held by Isaac Newton). Babbage's proposed Difference Engine was a special-purpose digital computing machine for the automatic production of mathematical tables (such as logarithm tables, tide tables, and astronomical tables). The Difference Engine consisted entirely of mechanical components -

brass gear wheels, rods, ratchets, pinions, etc. Numbers were represented in the decimal system by the positions of 10-toothed metal wheels mounted in columns. Babbage exhibited a small working model in 1822. He never completed the full-scale machine that he had designed but did complete several fragments. The largest - one ninth of the complete calculator - is on display in the London Science Museum. Baabage used it to perform serious computational work, calculating various mathematical tables. In 1990, Babbage's Difference Engine No. 2 was finally built from Babbage's designs and is also on display at the London Science Museum.

The Swedes Georg and Edvard Scheutz (father and son) constructed a modified version of Babbage's Difference Engine. Three were made, a prototype and two commercial models, one of these being sold to an observatory in Albany, New York, and the other to the Registrar-General's office in London, where it calculated and printed actuarial tables.

Babbage's proposed Analytical Engine, considerably more ambitious than the Difference Engine, was to have been a general-purpose mechanical digital computer. The Analytical Engine was to have had a memory store and a central processing unit (or ‘mill’) and would have been able to select from among alternative actions consequent upon the outcome of its previous actions (a facility nowadays known as conditional branching). The behaviour of the Analytical Engine would have been controlled by a program of instructions contained on punched cards connected together with ribbons (an idea that Babbage had adopted from the Jacquard weaving loom). Babbage emphasised the generality of the Analytical Engine, saying ‘the conditions which enable a finite machine to make calculations of unlimited extent are fulfilled in the Analytical Engine’ (Babbage [1994], p. 97).

Babbage worked closely with Ada Lovelace, daughter of the poet Byron, after whom the modern programming language ADA is named. Lovelace foresaw the possibility of using the Analytical Engine for non-numeric computation, suggesting that the Engine might even be capable of composing elaborate pieces of music.

A large model of the Analytical Engine was under construction at the time of Babbage's death in 1871 but a full-scale version was never built. Babbage's idea of a general-purpose calculating engine was never forgotten, especially at Cambridge, and was on occasion a lively topic of mealtime discussion at the war-time headquarters of the Government Code and Cypher School, Bletchley Park, Buckinghamshire, birthplace of the electronic digital computer.

Analog computers

The earliest computing machines in wide use were not digital but analog. In analog representation, properties of the representational medium ape (or reflect or model) properties of the represented state-of-affairs. (In obvious contrast, the strings of binary digits employed in digital representation do *not* represent by means of possessing some physical property - such as length - whose magnitude varies in proportion to the magnitude of the property that is being represented.) Analog representations form a diverse class. Some examples: the longer a line on a motorway map, the longer the road that the line

represents; the greater the number of clear plastic squares in an architect's model, the greater the number of windows in the building represented; the higher the pitch of an acoustic depth meter, the shallower the water. In analog computers, numerical quantities are represented by, for example, the angle of rotation of a shaft or a difference in electrical potential. Thus the output voltage of the machine at a time might represent the momentary speed of the object being modelled.

As the case of the architect's model makes plain, analog representation may be *discrete* in nature (there is no such thing as a fractional number of windows). Among computer scientists, the term ‘analog’ is sometimes used narrowly, to indicate representation of one *continuously-valued* quantity by another (e.g. speed by voltage). As Brian Cantwell Smith has remarked:

> "Analog" should ... be a predicate on a representation whose structure corresponds to that of which it represents ... That continuous representations should historically have come to be called analog presumably betrays the recognition that, at the levels at which it matters to us, the world is more foundationally continuous than it is discrete. (Smith [1991], p. 271)

James Thomson, brother of Lord Kelvin, invented the mechanical wheel-and-disc integrator that became the foundation of analog computation (Thomson [1876]). The two brothers constructed a device for computing the integral of the product of two given functions, and Kelvin described (although did not construct) general-purpose analog machines for integrating linear differential equations of any order and for solving simultaneous linear equations. Kelvin's most successful analog computer was his tide predicting machine, which remained in use at the port of Liverpool until the 1960s. Mechanical analog devices based on the wheel-and-disc integrator were in use during World War I for gunnery calculations. Following the war, the design of the integrator was considerably improved by Hannibal Ford (Ford [1919]).

Stanley Fifer reports that the first semi-automatic mechanical analog computer was built in England by the Manchester firm of Metropolitan Vickers prior to 1930 (Fifer [1961], p. 29); however, I have so far been unable to verify this claim. In 1931, Vannevar Bush, working at MIT, built the differential analyser, the first large-scale automatic general-purpose mechanical analog computer. Bush's design was based on the wheel and disc integrator. Soon copies of his machine were in use around the world (including, at Cambridge and Manchester Universities in England, differential analysers built out of kit-set Meccano, the once popular engineering toy).

It required a skilled mechanic equipped with a lead hammer to set up Bush's mechanical differential analyser for each new job. Subsequently, Bush and his colleagues replaced the wheel-and-disc integrators and other mechanical components by electromechanical, and finally by electronic, devices.

A differential analyser may be conceptualised as a collection of ‘black boxes’ connected together in such a way as to allow considerable feedback. Each box performs a fundamental process, for example addition, multiplication of a variable by a constant, and integration. In setting up the machine for a given task, boxes are connected together so that the desired set of fundamental processes is executed. In the case of electrical machines, this was done typically by plugging wires into sockets on a patch panel (computing

machines whose function is determined in this way are referred to as ‘program-controlled’).

Since all the boxes work in parallel, an electronic differential analyser solves sets of equations very quickly. Against this has to be set the cost of massaging the problem to be solved into the form demanded by the analog machine, and of setting up the hardware to perform the desired computation. A major drawback of analog computation is the higher cost, relative to digital machines, of an increase in precision. During the 1960s and 1970s, there was considerable interest in ‘hybrid’ machines, where an analog section is controlled by and programmed via a digital section. However, such machines are now a rarity.

The Universal Turing Machine

In 1935, at Cambridge University, Turing invented the principle of the modern computer. He described an abstract digital computing machine consisting of a limitless memory and a scanner that moves back and forth through the memory, symbol by symbol, reading what it finds and writing further symbols (Turing [1936]). The actions of the scanner are dictated by a program of instructions that is stored in the memory in the form of symbols. This is Turing's stored-program concept, and implicit in it is the possibility of the machine operating on and modifying its own program. (In London in 1947, in the course of what was, so far as is known, the earliest public lecture to mention computer intelligence, Turing said, "What we want is a machine that can learn from experience", adding that the "possibility of letting the machine alter its own instructions provides the mechanism for this" (Turing [1947] p. 123). Turing's computing machine of 1935 is now known simply as the universal Turing machine. Cambridge mathematician Max Newman has remarked that right from the start Turing was interested in the possibility of actually building a computing machine of the sort that he had described (Newman in interview with Christopher Evans in Evans [1976].

During the Second World War, Turing was a leading cryptanalyst at the Government Code and Cypher School, Bletchley Park. Here he became familiar with Thomas Flowers' work involving large-scale high-speed electronic switching (described below). However, Turing could not turn to the project of building an electronic stored-program computing machine until the cessation of hostilities in Europe in 1945.

Turing did give considerable thought to the question of machine intelligence during the wartime years. Colleagues at Bletchley Park recall numerous off-duty discussions with him on the topic, and at one point Turing circulated a typewritten report (now lost) setting out some of his ideas. One of these colleagues, Donald Michie (who later founded the Department of Machine Intelligence and Perception at the University of Edinburgh), remembers Turing talking often about the possibility of computing machines (1) learning from experience and (2) solving problems by means of searching through the space of possible solutions, guided by rule-of-thumb principles (Michie in interview with Copeland, 1995 and 1998). The modern term for the latter idea is ‘heuristic search’, a heuristic being any rule-of-thumb principle that cuts down the amount of searching required in order to find a solution to a problem. At Bletchley Park Turing illustrated his ideas on machine intelligence by reference to chess. Michie recalls Turing experimenting with heuristics that later became common in chess programming (in particular minimax and best-first).

Electromechanical versus Electronic Computation

With some exceptions - including Babbage's purely mechanical engines, and the finger-powered National Accounting Machine - early digital computing machines were electromechanical. That is to say, their basic components were small, electrically-driven, mechanical switches called ‘relays’. These operate relatively slowly, whereas the basic components of an electronic computer -- originally vacuum tubes (valves) -- have no moving parts save electrons and so operate extremely fast. Electromechanical digital computing machines were built before and during the second world war by (among others) Howard Aiken at Harvard University, George Stibitz at Bell Telephone Laboratories, Turing at Princeton University and Bletchley Park, and Konrad Zuse in Berlin. To Zuse belongs the honour of having built the first working general-purpose program-controlled digital computer. This machine, later called the Z3, was functioning in 1941. (A program-controlled computer, as opposed to a stored-program computer, is set up for a new task by re-routing wires, by means of plugs etc.)

Relays were too slow and unreliable a medium to make practicable the construction of a large-scale general-purpose digital computer (notwithstanding valiant efforts in this direction by Aiken). It was the development of high-speed digital techniques using vacuum tubes that made the modern computer possible.

The earliest extensive use of vacuum tubes for digital data-processing appears to have been by the engineer Thomas Flowers, working in London at the British Post Office Research Station at Dollis Hill. (Material in this article concerning Flowers derives from personal communications from Flowers to Copeland (1996-8) and a tape-recorded interview between Flowers and Evans (see Evans [1976]). Electronic digital equipment designed by Flowers in 1934, for controlling the connections between telephone exchanges, went into operation in 1939, and involved between three and four thousand vacuum tubes running continuously. In 1938-1939 Flowers worked on an experimental high-speed electronic digital data-processing system, involving a data store. Flowers' aim, achieved after the war, was that such equipment should replace existing, less reliable, systems built from relays and used in telephone exchanges. Flowers did not investigate the idea of using electronic equipment for numerical calculation, but has remarked that at the outbreak of war with Germany in 1939 he was possibly the only person in Britain who realized that vacuum tubes could be used on a large scale for high-speed digital computation.

Atanasoff

The earliest comparable use of vacuum tubes in the U.S. seems to have been by John Atanasoff at what was then Iowa State College (now University). During the period 1937-1942 Atanasoff developed techniques for using vacuum tubes to perform numerical calculations digitally. In 1939, with the assistance of his student Clifford Berry, Atanasoff began building what is sometimes called the Atanasoff-Berry Computer, or ABC, a small-scale special-purpose electronic digital machine for the solution of systems of linear algebraic equations. The machine contained approximately 300 vacuum tubes. Although the electronic part of the machine functioned successfully, the computer as a whole never worked reliably,

errors being introduced by the unsatisfactory binary card-reader. Work was discontinued in 1942 when Atanasoff left Iowa State.

Colossus

The first fully functioning electronic digital computer was Colossus (1943), used by the Bletchley Park cryptanalysts from 1944.

From very early in the war the Government Code and Cypher School (GC&CS) was successfully deciphering German radio communications encoded by means of the Enigma system, and by early 1942 about 39,000 intercepted messages were being decoded each month, thanks to electromechanical machines known as ‘bombes’. These were designed by Turing and Gordon Welchman (building on earlier work by Polish cryptanalysts).

During the second half of 1940, messages encoded by means of a totally different method began to be intercepted. This new method of encryption, named ‘Fish’ by GC&CS, remained intractable until 1941 (the first major break-in occurring at the end of August 1941); current traffic was read for the first time in July 1942. Based on binary teleprinter code, Fish was used in preference to Morse-based Enigma for the encryption of high-level signals, for example messages from Hitler and other members of the German High Command.

The need to decipher this vital intelligence as rapidly as possible led Max Newman to propose in November 1942 (shortly after his recruitment to GC&CS from Cambridge University) that key parts of the decryption process be automated, by means of high-speed electronic counting devices. The first machine designed and built to Newman's specification, known as the Heath Robinson, was relay-based with electronic circuits for counting. (The electronic counters were designed by C.E. Wynn-Williams, who had been using thyratron tubes in counting circuits at the Cavendish Laboratory, Cambridge, since 1932 [Wynn-Williams 1932].) Installed in June 1943, Heath Robinson was unreliable and slow, and its high-speed paper tapes were continually breaking, but it proved the worth of Newman's method. Turing recommended that Newman approach Flowers - who had previously assisted with the design of a machine for use against Enigma - to improve the reliability of the Robinson. Flowers offered instead to design and build a fully electronic machine with a similar function to Heath Robinson. Flowers received little official encouragement from GC&CS but proceeded nonetheless, working independently at the Post Office Research Station at Dollis Hill. Colossus I was installed at Bletchley Park on 8 December 1943.

In all, ten Colossi were built. From a cryptanalytic viewpoint, a major difference between the prototype Colossus I and the later machines was the addition of the so-called Special Attachment, consequent upon a key discovery by cryptanalysts Donald Michie and Jack Good. This broadened the function of Colossus from ‘wheel setting’ - i.e. determining the settings of the encoding wheels of the German Lorenz cipher machine for a particular message, given the ‘patterns’ of the wheels - to ‘wheel breaking’, i.e. determining the wheel patterns themselves. The wheel patterns were eventually changed daily by the Germans on each of the numerous links between Berlin and strategically critical remote stations, notably the various Army

Group commanders in the field. By 1945 there were as many 30 links in total. About ten of these were broken and read regularly.

Colossus I contained approximately 1600 vacuum tubes and each of the subsequent machines approximately 2400 vacuum tubes. Like the smaller ABC, Colossus lacked two important features of modern computers. First, it had no internally stored programs. To set it up for a new task, the operator had to alter the machine's physical wiring, using plugs and switches. Second, Colossus was not a general-purpose machine, being designed for a specific cryptanalytic task involving counting and Boolean operations.

The magnificent working model presently on display at Bletchley Park, now a museum, is a mock-up of Colossus I.

F.H. Hinsley, official historian of GC&CS, has estimated that the war in Europe was shortened by at least two years as a result of the signals intelligence operation carried out at Bletchley Park, in which Colossus played a major role. Most of the Colossi were destroyed once hostilities ceased. Some of the electronic panels ended up at Newman's Computing Machine Laboratory in Manchester (see below), all trace of their original use having been removed, At least one Colossus was retained by GCHQ, the successor organisation to GC&CS. The last Colossus stopped running in 1960 (during its later years, it was used extensively for training).

Those who knew of Colossus were prohibited by the Official Secrets Act from sharing their knowledge. Until the 1970s, few had any idea that electronic computation had been used successfully during the second world war. In 1970 and 1975, respectively, Good and Michie published notes giving the barest outlines of Colossus. By 1983, Flowers had received clearance from the British Government to publish a full account of the hardware of Colossus I. Details of the later machines and of the Special Attachment, the uses to which the Colossi were put, and the cryptanalytic algorithms that they ran, were not declassified until 1996. Even today some documents remain classified.

For those acquainted with the universal Turing machine of 1935, and the associated stored-program concept, Flowers' racks of digital electronic equipment indicated the feasibility of using large numbers of vacuum tubes to implement a high-speed general-purpose stored-program digital computing machine. The war over, Newman lost no time in establishing the Royal Society Computing Machine Laboratory at Manchester University for precisely that purpose. A few months after his arrival at Manchester, Newman wrote as follows to the Princeton mathematician John von Neumann (February 1946):

> I am ... hoping to embark on a computing machine section here, having got very interested in electronic devices of this kind during the last two or three years. By about eighteen months ago I had decided to try my hand at starting up a machine unit when I got out. ... I am of course in close touch with Turing.

Turing's Automatic Computing Engine

Turing and Newman were thinking along similar lines. In 1945 Turing joined the National Physical Laboratory (NPL) in London, his brief to design and develop an electronic stored-program digital computer for scientific work. (Artificial Intelligence was not far from Turing's thoughts: he described himself as ‘building a brain’ and remarked in a letter that he was ‘more interested in the possibility of producing models of the action of the brain than in the practical applications to computing’.) John Womersley, Turing's immediate superior at NPL, christened Turing's proposed machine the Automatic Computing Engine, or ACE, in homage to Babbage's Difference Engine and Analytical Engine.

Turing's ‘Proposal for Development in the Mathematics Division of an Automatic Computing Engine (ACE)’ was the first relatively complete specification of an electronic stored-program general-purpose digital computer. An NPL file (now unfortunately destroyed) gave the date of Turing's proposal as 1945; Michael Woodger, Turing's assistant at NPL from May 1946, believes that the proposal was probably written between October and December 1945. (The proposal is reprinted in full in the collection (Carpenter and Doran [1986]). See also Copeland [1998].)

The first electronic stored-program digital computer to be proposed in the U.S. was the EDVAC (see below). The ‘First Draft of a Report on the EDVAC’ (May 1945), composed by von Neumann, contained little engineering detail, in particular concerning electronic hardware (owing to restrictions in the U.S.). Turing's proposal, on the other hand, supplied detailed circuit designs and specifications of hardware units, specimen programs in machine code, and even an estimate of the cost of building the machine (£11,200). ACE and EDVAC differed fundamentally from one another; for example, ACE employed distributed processing, while EDVAC had a centralised structure.

Turing saw that speed and memory were the keys to computing. (Turing's colleague at NPL, Jim Wilkinson, has observed that Turing ‘was obsessed with the idea of speed on the machine’ (in interview with Evans [1976]).) Turing's design had much in common with today's RISC architectures and it called for a high-speed memory of roughly the same capacity as an early Macintosh computer (enormous by the standards of his day). Had Turing's ACE been built as planned it would have been in a different league from the other early computers. However, progress on Turing's Automatic Computing Engine ran slowly, due to organisational difficulties at NPL, and in 1948 a ‘very fed up’ Turing (Robin Gandy's description, in interview with Copeland, 1995) left NPL for Newman's Computing Machine Laboratory at Manchester University. It was not until May 1950 that a small pilot model of the Automatic Computing Engine, built by Wilkinson, Edward Newman, Woodger, and others, first executed a program. With an operating speed of 1 MHz, the Pilot Model ACE was for some time the fastest computer in the world (Woodger in interview with Copeland, 1998).

Sales of DEUCE, the production version of the Pilot Model ACE, exceeded 30 (confounding a prediction by a top adviser to NPL that Britain's computing needs would be satisfied by a total of three digital computers (NPL archives)). The fundamentals of Turing's ACE design were employed by Harry Huskey (at Wayne State University, Detroit) in the Bendix G15 computer (Huskey in interview with Copeland, 1998). The G15 was arguably the first personal computer; over 400 were sold worldwide. DEUCE and the G15 remained in use until about 1970. Another computer deriving from Turing's ACE design, the

MOSAIC, played a role in Britain's air defences during the Cold War period; other derivatives include the Packard-Bell PB250 (1961).

The Manchester Machine

The earliest general-purpose stored-program electronic digital computer to work was built in the Royal Society Computing Machine Laboratory at Manchester University. The Manchester ‘Baby’, as it became known, was constructed by the engineers F.C. Williams and Tom Kilburn, and performed its first calculation on 21 June 1948. The tiny program, stored on the face of a cathode ray tube, was just seventeen instructions long. A much enlarged version of the machine, with a programming system designed by Turing, became the world's first commercially available computer, the Ferranti Mark I. The first to be completed was installed at Manchester University in February 1951; in all about ten were sold, in Britain, Canada, Holland and Italy.

The fundamental logico-mathematical contributions by Turing and Newman to the triumph at Manchester have been neglected, and the Manchester machine is nowadays remembered as the work of Williams and Kilburn. Indeed, Newman's role in the development of computers has never been sufficiently emphasised (due perhaps to his thoroughly self-effacing way of relating the relevant events).

It was Newman who, in a lecture in Cambridge in 1935, introduced Turing to the concept which led directly to the Turing machine: Newman defined a constructive process as one that a *machine* can carry out (Newman in interview with Evans, op. cit.). As a result of his acquaintance with Turing's work of 1935-36, Newman became interested in the possibilities of computing machinery in, as he put it, ‘a rather theoretical way’. It was not until Newman joined GC&CS in 1942 that his interest in computing machinery suddenly became practical, with his realisation that the attack on Fish could be mechanised. During the building of Colossus, Newman tried to interest Flowers in Turing's 1936 paper - birthplace of the stored-program concept - but Flowers (in his own words) ‘didn't really understand much of it’. There can be little doubt that by 1943, Newman had firmly in mind the idea of using electronic technology in order to construct a stored-program general-purpose digital computing machine.

In July of 1946 (the month in which the Royal Society approved Newman's application for funds to found the Computing Machine Laboratory), Freddie Williams, working at the Telecommunications Research Establishment, Malvern, began the series of experiments on cathode ray tube storage that was to lead to the Williams tube memory. Williams, until then a radar engineer, explains how it was that he came to be working on the problem of computer memory:

> [O]nce [the German Armies] collapsed ... nobody was going to care a toss about radar, and people like me ... were going to be in the soup unless we found something else to do. And computers were in the air. Knowing absolutely nothing about them I latched onto the problem of storage and tackled that. (Quoted in Bennett [unpublished].)

Newman learned of Williams' work, and there seems little doubt that Newman, with the able help of

Patrick Blackett, Langworthy Professor of Physics at Manchester and one of the most powerful figures in the University, was instrumental in the appointment of the 35 year old Williams to the recently vacated Chair of Electro-Technics at Manchester. (Newman himself was a member of the appointing committee (Tom Kilburn in interview with Copeland, 1997).) Williams immediately had Kilburn, his assistant at Malvern, seconded to Manchester. To take up the story in Williams' own words:

> [N]either Tom Kilburn nor I knew the first thing about computers when we arrived in Manchester University. We'd had enough explained to us to understand what the problem of storage was and what we wanted to store, and that we'd achieved, so the point now had been reached when we'd got to find out about computers ... Newman explained the whole business of how a computer works to us. (F.C. Williams in interview with Evans [1976])

Elsewhere Williams is explicit concerning Turing's role and gives something of the flavour of the explanation that he and Kilburn received:

> Tom Kilburn and I knew nothing about computers, but a lot about circuits. Professor Newman and Mr A.M. Turing ... knew a lot about computers and substantially nothing about electronics. [This is not entirely fair to Turing. BJC] They took us by the hand and explained how numbers could live in houses with addresses and how if they did they could be kept track of during a calculation. (Williams [1975], p. 328)

It seems that Newman must have used much the same words with Williams and Kilburn as he did in an address to the Royal Society on 4th March 1948:

> Professor Hartree ... has recalled that all the essential ideas of the general-purpose calculating machines now being made are to be found in Babbage's plans for his analytical engine. In modern times the idea of a universal calculating machine was independently introduced by Turing ... [T]he machines now being made in America and in this country ... [are] in certain general respects ... all similar. There is provision for storing numbers, say in the scale of 2, so that each number appears as a row of, say, forty 0's and 1's in certain places or "houses" in the machine. ... Certain of these numbers, or "words" are read, one after another, as orders. In one possible type of machine an order consists of four numbers, for example 11, 13, 27, 4. The number 4 signifies "add", and when control shifts to this word the "houses" H11 and H13 will be connected to the adder as inputs, and H27 as output. The numbers stored in H11 and H13 pass through the adder, are added, and the sum is passed on to H27. The control then shifts to the next order. In most real machines the process just described would be done by three separate orders, the first bringing [H11] (=content of H11) to a central accumulator, the second adding [H13] into the accumulator, and the third sending the result to H27; thus only one address would be required in each order. ... A machine with storage, with this automatic-telephone-exchange arrangement and with the necessary adders, subtractors and so on, is, in a sense, already a universal machine. (Newman [1948], pp. 271-272)

Newman goes on to explain program storage ('the orders shall be in a series of houses X1, X2, ...') and conditional branching. He then sums up:

> From this highly simplified account it emerges that the essential internal parts of the machine are, first, a storage for numbers (which may also be orders). ... Secondly, adders, multipliers, etc. Thirdly, an "automatic telephone exchange" for selecting "houses", connecting them to the arithmetic organ, and writing the answers in other prescribed houses. Finally, means of moving control at any stage to any chosen order, if a certain condition is satisfied, otherwise passing to the next order in the normal sequence. Besides these there must be ways of setting up the machine at the outset, and extracting the final answer in useable form. (Newman [1948], pp. 273-4)

There seems little doubt that the major credit for the Manchester machine belongs not only to Williams and Kilburn but also to Newman, and that the influence upon Newman of Turing's paper of 1936, which first set out the concept of the stored-program universal digital computer, was crucial.

The first working AI program, a draughts (checkers) player written by Christopher Strachey, ran on the Ferranti Mark I in the Manchester Computing Machine Laboratory. Strachey (at the time a teacher at Harrow School and an amateur programmer) wrote the program with Turing's encouragement and utilising the latter's recently completed Programmers' Handbook for the Ferranti. (Strachey later became Director of the Programming Research Group at Oxford University.) By the summer of 1952, the program could, Strachey reported, 'play a complete game of draughts at a reasonable speed'. (Strachey's program formed the basis for Arthur Samuel's well-known checkers program.) The first chess-playing program, also, was written for the Manchester Ferranti, by Dietrich Prinz; the program first ran in November 1951. Designed for solving simple problems of the mate-in-two variety, the program would examine every possible move until a solution was found. Turing started to program his 'Turochamp' chess-player on the Ferranti Mark I, but never completed the task. Unlike Prinz's program, the Turochamp could play a complete game (when hand-simulated) and operated not by exhaustive search but under the guidance of heuristics.

ENIAC and EDVAC

The first fully functioning electronic digital computer to be built in the U.S. was ENIAC, constructed at the Moore School of Electrical Engineering, University of Pennsylvania, for the Army Ordnance Department, by J. Presper Eckert and John Mauchly. Completed in 1945, ENIAC was somewhat similar to the earlier Colossus, but considerably larger and more flexible (although far from general-purpose). The primary function for which ENIAC was designed was the calculation of tables used in aiming artillery. ENIAC was not a stored-program computer, and setting it up for a new job involved reconfiguring the machine by means of plugs and switches. For many years, ENIAC was believed to have been the first functioning electronic digital computer, Colossus being unknown to all but a few.

In 1944, John von Neumann joined the ENIAC group. He had become 'intrigued' (Goldstine's word,

[1972], p. 275) with Turing's universal machine while Turing was at Princeton University during 1936-1938. At the Moore School, von Neumann emphasised the importance of the stored-program concept for electronic computing, including the possibility of allowing the machine to modify its own program in useful ways while running (for example, in order to control loops and branching). Turing's paper of 1936 (‘On Computable Numbers, with an Application to the Entscheidungsproblem’) was required reading for members of von Neumann's post-war computer project at the Institute for Advanced Study, Princeton University (Julian Bigelow in personal communication with William Aspray, reported in the Aspray [1990], pp. 178, 313). Eckert appears to have realised independently, and prior to von Neumann's joining the ENIAC group, that the way to take full advantage of the speed at which data is processed by electronic circuits is to place suitably encoded instructions for controlling the processing in the same high-speed storage devices that hold the data itself (Huskey in interview with Copeland, 1998). In 1945, while ENIAC was still under construction, von Neumann produced a draft report, mentioned previously, setting out the ENIAC group's ideas for an electronic stored-program general-purpose digital computer, the EDVAC (von Neuman [1945]). The EDVAC was completed six years later, but not by its originators, who left the Moore School to build computers elsewhere. Lectures held at the Moore School in 1946 on the proposed EDVAC were widely attended and contributed greatly to the dissemination of the new ideas.

Von Neumann was a prestigious figure and he made the concept of a high-speed stored-program digital computer widely known through his writings and public addresses. As a result of his high profile in the field, it became customary, although historically inappropriate, to refer to electronic stored-program digital computers as ‘von Neumann machines’.

The Los Alamos physicist Stanley Frankel, responsible with von Neumann and others for mechanising the large-scale calculations involved in the design of the atomic bomb, has described von Neumann's view of the importance of Turing's 1936 paper, in a letter to the historian Brian Randell:

> I know that in or about 1943 or ‘44 von Neumann was well aware of the fundamental importance of Turing's paper of 1936 ... Von Neumann introduced me to that paper and at his urging I studied it with care. Many people have acclaimed von Neumann as the "father of the computer" (in a modern sense of the term) but I am sure that he would never have made that mistake himself. He might well be called the midwife, perhaps, but he firmly emphasized to me, and to others I am sure, that the fundamental conception is owing to Turing, in so far as not anticipated by Babbage ... Both Turing and von Neumann, of course, also made substantial contributions to the "reduction to practice" of these concepts but I would not regard these as comparable in importance with the introduction and explication of the concept of a computer able to store in its memory its program of activities and of modifying that program in the course of these activities. (Quoted in Randell [1972], p. 10)

Other Notable Early Computers

Other notable early stored-program electronic digital computers were:

- EDSAC, 1949, built at Cambridge University by Maurice Wilkes
- BINAC, 1949, built by Eckert's and Mauchly's Electronic Control Co., Philadelphia (opinions differ over whether BINAC ever actually worked)
- Whirlwind I, 1949, Digital Computer Laboratory, Massachusetts Institute of Technology, Jay Forrester
- SEAC, 1950, US Bureau of Standards Eastern Division, Washington D.C., Samuel Alexander, Ralph Slutz
- SWAC, 1950, US Bureau of Standards Western Division, Institute for Numerical Analysis, University of California at Los Angeles, Harry Huskey
- UNIVAC, 1951, Eckert-Mauchly Computer Corporation, Philadelphia (the first computer to be available commercially in the U.S.)
- the IAS computer, 1952, Institute for Advanced Study, Princeton University, Julian Bigelow, Arthur Burks, Herman Goldstine, von Neumann, and others (thanks to von Neumann's publishing the specifications of the IAS machine, it became the model for a group of computers known as the Princeton Class machines; the IAS computer was also a strong influence on the IBM 701)
- IBM 701, 1952, International Business Machine's first mass-produced electronic stored-program computer.

High-Speed Memory

The EDVAC and ACE proposals both advocated the use of mercury-filled tubes, called ‘delay lines’, for high-speed internal memory. This form of memory is known as acoustic memory. Delay lines had initially been developed for echo cancellation in radar; the idea of using them as memory devices originated with Eckert at the Moore School. Here is Turing's description:

> It is proposed to build "delay line" units consisting of mercury ... tubes about 5′ long and 1″ in diameter in contact with a quartz crystal at each end. The velocity of sound in ... mercury ... is such that the delay will be 1.024 ms. The information to be stored may be considered to be a sequence of 1024 ‘digits’ (0 or 1) ... These digits will be represented by a corresponding sequence of pulses. The digit 0 ... will be represented by the absence of a pulse at the appropriate time, the digit 1 ... by its presence. This series of pulses is impressed on the end of the line by one piezo-crystal, it is transmitted down the line in the form of supersonic waves, and is reconverted into a varying voltage by the crystal at the far end. This voltage is amplified sufficiently to give an output of the order of 10 volts peak to peak and is used to gate a standard pulse generated by the clock. This pulse may be again fed into the line by means of the transmitting crystal, or we may feed in some altogether different signal. We also have the possibility of leading the gated pulse to some other part of the calculator, if we have need of that information at the time. Making use of the information does not of course preclude keeping it also. (Turing [1945], p. 24)

Mercury delay line memory was used in EDSAC, BINAC, SEAC, Pilot Model ACE, EDVAC, DEUCE,

and full-scale ACE (1958). The chief advantage of the delay line as a memory medium was, as Turing put it, that delay lines were "already a going concern" (Turing [1947], p. 108). The fundamental disadvantages of the delay line were that random access is impossible and, moreover, the time taken for an instruction, or number, to emerge from a delay line depends on where in the line it happens to be.

In order to minimize waiting-time, Turing arranged for instructions to be stored not in consecutive positions in the delay line, but in relative positions selected by the programmer in such a way that each instruction would emerge at exactly the time it was required, in so far as this was possible. Each instruction contained a specification of the location of the next. This system subsequently became known as ‘optimum coding’. It was an integral feature of every version of the ACE design. Optimum coding made for difficult and untidy programming, but the advantage in terms of speed was considerable. Thanks to optimum coding, the Pilot Model ACE was able to do a floating point multiplication in 3 milliseconds (Wilkes's EDSAC required 4.5 milliseconds to perform a single fixed point multiplication).

In the Williams tube or electrostatic memory, previously mentioned, a two-dimensional rectangular array of binary digits was stored on the face of a commercially-available cathode ray tube. Access to data was immediate. Williams tube memories were employed in the Manchester series of machines, SWAC, the IAS computer, and the IBM 701, and a modified form of Williams tube in Whirlwind I (until replacement by magnetic core in 1953).

Drum memories, in which data was stored magnetically on the surface of a metal cylinder, were developed on both sides of the Atlantic. The initial idea appears to have been Eckert's. The drum provided reasonably large quantities of medium-speed memory and was used to supplement a high-speed acoustic or electrostatic memory. In 1949, the Manchester computer was successfully equipped with a drum memory; this was constructed by the Manchester engineers on the model of a drum developed by Andrew Booth at Birkbeck College, London.

The final major event in the early history of electronic computation was the development of magnetic core memory. Jay Forrester realised that the hysteresis properties of magnetic core (normally used in transformers) lent themselves to the implementation of a three-dimensional solid array of randomly accessible storage points; in 1949, at Massachusetts Institute of Technology, he began to investigate this idea empirically. Forrester's early experiments with metallic core soon led him to develop the superior ferrite core memory (Forrester in interview with Evans, op. cit.). Digital Equipment Corporation undertook to build a computer similar to the Whirlwind I as a test vehicle for a ferrite core memory. The Memory Test Computer was completed in 1953. (This computer was used in 1954 for the first simulations of neural networks, by Belmont Farley and Wesley Clark of MIT's Lincoln Laboratory (see Copeland and Proudfoot [1996]).

Once the absolute reliability, relative cheapness, high capacity and permanent life of ferrite core memory became apparent, core soon replaced other forms of high-speed memory. The IBM 704 and 705 computers (announced in May and October 1954, respectively) brought core memory into wide use.

Connectionism

Connectionism is a movement in cognitive science which hopes to explain human intellectual abilities using artificial neural networks (also known as ‘neural networks’ or ‘neural nets’). Neural networks are simplified models of the brain composed of large numbers of units (the analogs of neurons) together with weights that measure the strength of connections between the units. These weights model the effects of the synapses that link one neuron to another. Experiments on models of this kind have demonstrated an ability to learn such skills as face recognition, reading, and the detection of simple grammatical structure.

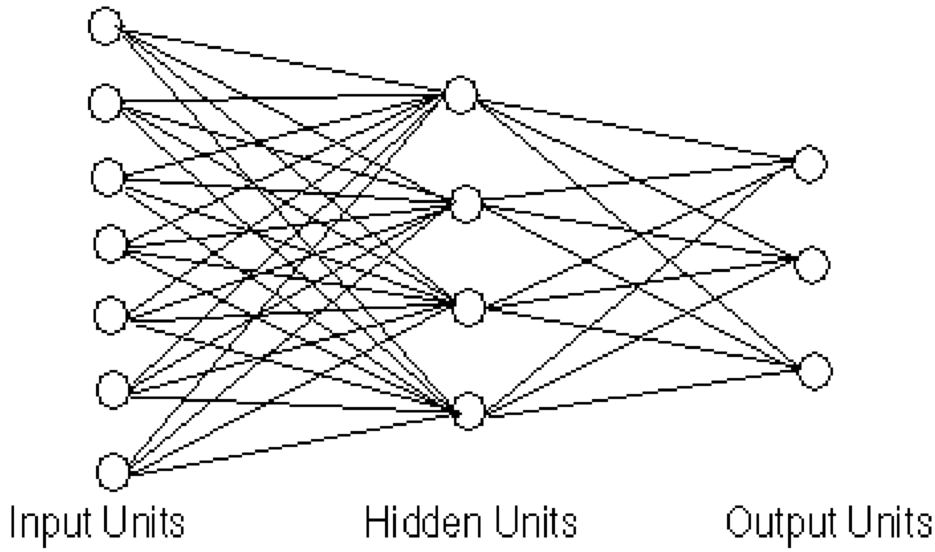
Philosophers have become interested in connectionism because it promises to provide an alternative to the classical theory of the mind: the widely held view that the mind is something akin to a digital computer processing a symbolic language. Exactly how and to what extent the connectionist paradigm constitutes a challenge to classicism has been a matter of hot debate in recent years.

A Description of Neural Networks

A neural network consists of large number of units joined together in a pattern of connections. Units in a net are usually segregated into three classes: input units, which receive information to be processed, output units where the results of the processing are found, and units in between called hidden units. If a neural net were to model the whole human nervous system, the input units would be analogous to the

sensory neurons, the output units to the motor neurons, and the hidden units to all other neurons.

Here is a simple illustration of a neural net:



Each input unit has an activation value that represents some feature external to the net. An input unit sends its activation value to each of the hidden units to which it is connected. Each of these hidden units calculates its own activation value depending on the activation values it receives from the input units. This signal is then passed on to output units or to another layer of hidden units. Those hidden units compute their activation values in the same way, and send them along to their neighbors. Eventually the signal at the input units propagates all the way through the net to determine the activation values at all the output units.

The pattern of activation set up by a net is determined by the weights, or strength of connections between the units. Weights may be both positive or negative. A negative weight represents the inhibition of the receiving unit by the activity of a sending unit. The activation value for each receiving unit is calculated according a simple activation function. Activation functions vary in detail, but they all conform to the same basic plan. The function sums together the contributions of all sending units, where the contribution of a unit is defined as the weight of the connection between the sending and receiving units times the sending unit's activation value. This sum is usually modified further, for example, by adjusting the activation sum to a value between 0 and 1 and/or by setting the activation to zero unless a threshold level for the sum is reached. Connectionists presume that cognitive functioning can be explained by collections of units that operate in this way. Since it is assumed that all the units calculate pretty much the same simple activation function, human intellectual accomplishments must depend primarily on the settings of the weights between the units.

Neural Network Learning and Backpropagation

Finding the right set of weights to accomplish a given task is the central goal in connectionist research.

Luckily, learning algorithms have been devised that can calculate the right weights for carrying out many tasks. (See Hinton (1992) for an accessible review.) One of the most widely used of these training methods is called backpropagation. To use this method one needs a training set consisting of many examples of inputs and their desired outputs for a given task. If, for example, the task is to distinguish male from female faces, the training set might contain pictures of faces together with an indication of the sex of the person depicted in each one. A net that can learn this task might have two output units (indicating "male" and "female") and many input units, one devoted to the brightness of each pixel (tiny area) in the picture. The weights of the net to be trained are initially set to random values, and then members of the training set are repeatedly exposed to the net. The values for the input of a member are placed on the input units and the output of the net is compared with the desired output for this member. Then all the weights in the net are adjusted slightly in the direction that would bring the net's output values closer to the values for the desired output. For example, when male's face is presented to the input units the weights are adjusted so that the value of the "male" output unit is increased and the value of the "female" output unit is decreased. After many repetitions of this process the net may learn to produce the desired output for each input in the training set. If the training goes well, the net many also have learned to generalize to the desired behavior for inputs and outputs that were not in the training set. For example, it may do a good job of distinguishing males from females in pictures that were never presented to it before.

Training nets to model aspects of human intelligence is a fine art. Success with backpropagation and other connectionist learning methods may depend on quite subtle adjustment of the algorithm and the training set. Training typically involves hundreds of thousands of rounds of weight adjustment. Given the limitations of computers presently available to connectionist researchers, training a net to perform an interesting task may take days or even weeks. Some of the difficulty may be resolved when parallel circuits specifically designed to run neural network models are widely available. But even here, some limitations to connectionist theories of learning will remain to be faced. Humans (and many less intelligent animals) display an ability to learn from single events; for example an animal that eats a food that later causes gastric distress will never try that food again. Connectionist learning techniques such as backpropagation are far from explaining this kind of "one shot" learning.

Samples of What Neural Networks Can Do

Connectionists have made significant progress in demonstrating the power of neural networks to master cognitive tasks. Here are three well-known experiments that have encouraged connectionists to believe that neural networks are good models of human intelligence. One of the most attractive of these efforts is Sejnowski and Rosenberg's (1987) work on a net that can read English text called NETtalk. The training set for NETtalk was a large data base consisting of English text coupled with its corresponding phonetic output, written in a code suitable for use with a speech synthesizer. Tapes of NETtalk's performance at different stages of its training are very interesting listening. At first the output is random noise. Later, the net sounds like it is babbling, and later still as though it is speaking English double-talk (speech that is formed of sounds that resemble English words). At the end of training, NETtalk does a fairly good job of pronouncing the text given to it. Furthermore, this ability generalizes fairly well to text that was not

presented in the training set.

Another influential early connectionist model was a net trained by Rumelhart and McClelland (1986) to predict the past tense of English verbs. The task is interesting because although most of the verbs in English (the regular verbs) form the past tense by adding the suffix ‘ed’, many of the most frequently verbs are irregular (is / was, come / came, go / went). The net was first trained on a set containing a large number of irregular verbs, and later on a set of 460 verbs containing mostly regulars. The net learned the past tenses of the 460 verbs in about 200 rounds of training, and it generalized fairly well to verbs not in the training set. It even showed a good appreciation of "regularities" to be found among the irregular verbs (send / sent, build / built; blow / blew, fly / flew). During learning, as the system was exposed to the training set containing more regular verbs, it had a tendency to overregularize, i.e. to combine both irregular and regular forms: (break / broked, instead of break / broke). This was corrected with more training. It is interesting to note that children are known to exhibit the same tendency to overregularize during language learning. However, there is hot debate over whether Rumelhart and McClelland’s is a good model of how humans actually learn and process verb endings. For example, (Pinker & Prince 1988) point out that the model does a poor job of generalizing to some novel regular verbs. They believe that this is a sign of a basic failing in connectionist models. Nets may be good at making associations and matching patterns, but they have fundamental limitations in mastering general rules such as the formation of the regular past tense. These complaints raise an important issue for connectionist modelers, namely whether nets can generalize properly to master cognitive tasks involving rules. Despite Pinker and Prince’s objections, many connectionists believe that generalization of the right kind is still possible (Niklasson and van Gelder, 1994).

Elman’s (1991) work on nets that can appreciate grammatical structure has important implications for the debate about whether neural networks can learn to master rules. Elman trained a neural network to predict the next word in a large corpus of English sentences. The sentences were formed from a simple vocabulary of 23 words using a subset of English grammar. The grammar, though simple, posed a hard test for linguistic awareness. It allowed unlimited formation of relative clauses while demanding agreement between the head noun and the verb. So for example, in the sentence

> Any **man** that chases dogs that chase cats .. run**s**.

the singular ‘**man**’ must agree with the verb ‘run**s**’ despite the intervening plural nouns (‘dogs’, ‘cats’) which might cause the selection of ‘run’. One of the important features of Elman’s model is the use of recurrent connections. The values at the hidden units are saved in a set of so called context units, to be sent back to the input level for the next round of processing. This looping back from hidden to input layers provides the net with a rudimentary form of memory of the sequence of words in the input sentence. Elman’s nets displayed an appreciation of the grammatical structure of sentences that were not in the training set. The net’s command of syntax was measured in the following way. Predicting the next word in an English sentence is, of course, and impossible task. However, these nets succeeded, at least by the following measure. At a given point in an input sentence, the output units for words that are grammatical continuations of the sentence at that point should be active and output units for all other words should be inactive. After intensive training, Elman was able to produce nets that displayed perfect

performance on this measure including sentences not in the training set. Although this performance is impressive, there is still a long way to go in training nets that can process language. Furthermore, doubts have been raised about the significance of Elman's results. For example, Marcus (to appear) argues that Elman's nets are not able to generalize this performance to sentences formed from a novel vocabulary. This, he claims, is a sign that connectionist models merely associate instances, and are unable to truly master abstract rules.

Strengths and Weaknesses of Neural Network Models

Philosophers are interested in neural networks because they may provide a new framework for understanding the nature of the mind and its relation to the brain (Rumelhart and McClelland, 1986, Chapter 1). Connectionist models seem particularly well matched to what we know about neurology. The brain is indeed a neural net, formed from massively many units (neurons) and their connections (synapses). Furthermore, several properties of neural network models suggest that connectionism may offer an especially faithful picture of the nature of cognitive processing. Neural networks exhibit robust flexibility in the face of the challenges posed by the real world. Noisy input or destruction of units causes graceful degradation of function. The net's response is still appropriate, though somewhat less accurate. In contrast, noise and loss of circuitry in classical computers typically result in catastrophic failure. Neural networks are also particularly well adapted for problems that require the resolution of many conflicting constraints in parallel. There is ample evidence from research in artificial intelligence that cognitive tasks such as object recognition, planning, and even coordinated motion present problems of this kind. Although classical systems are capable of multiple constraint satisfaction, connectionists argue that neural network models provide much more natural mechanisms for dealing with such problems.

Over the centuries, philosophers have struggled to understand how our concepts are defined. It is now widely acknowledged that trying to characterize ordinary notions with necessary and sufficient conditions is doomed to failure. Exceptions to almost any proposed definition are always waiting in the wings. For example, one might propose that a tiger is a large black and orange feline. But then what about albino tigers? Philosophers and cognitive psychologists have argued that categories are delimited in more flexible ways, for example via a notion of family resemblance or similarity to a prototype. Connectionist models seem especially well suited to accommodating graded notions of category membership of this kind. Nets can learn to appreciate subtle statistical patterns that would be very hard to express as hard and fast rules. Connectionism promises to explain flexibility and insight found in human intelligence using methods that cannot be easily expressed in the form of exception free principles (Horgan and Tienson, 1989, 1990), thus avoiding the brittleness that arises from standard forms of symbolic representation.

Despite these intriguing features, there are some weaknesses in connectionist models that bear mentioning. First, most neural network research abstracts away from many interesting and possibly important features of the brain. For example, connectionists usually do not attempt to explicitly model the variety of different kinds of brain neurons, nor the effects of neurotransmitters and hormones.

Furthermore, it is far from clear that the brain contains the kind of reverse connections that would be needed if the brain were to learn by a process like backpropagation, and the immense number of repetitions needed for such training methods seems far from realistic. Attention to these matters will probably be necessary if convincing connectionist models of human cognitive processing are to be constructed. A more serious objection must also be met. It is widely felt, especially among classicists, that neural networks are not particularly good at the kind of rule based processing that is thought to undergird language, reasoning, and higher forms of thought. We will discuss the matter further when we turn to the systematicity debate.

Connectionist Representation

Connectionist models provide a new paradigm for understanding how information might be represented in the brain. A seductive but naive idea is that single neurons (or tiny neural bundles) might be devoted to the representation of each thing the brain needs to record. For example, we may imagine that there is a grandmother neuron that fires when we think about our grandmother. However, such local representation is not likely. There is good evidence that our grandmother thought involves complex patterns of activity distributed across relatively large parts of cortex.

It is interesting to note that distributed, rather than local representations on the hidden units are the natural products of connectionist training methods. The activation patterns that appear on the hidden units while NETtalk processes text serve as an example. Analysis reveals that the net learned to represent such categories as consonants and vowels, not by creating one unit active for consonants and another for vowels, but rather in developing two different characteristic patterns of activity across all the hidden units.

Given the expectations formed from our experience with local representation on the printed page, distributed representation seems both novel and difficult to understand. But the technique exhibits important advantages. For example, distributed representations, (unlike symbols stored in separate fixed memory locations) remain relatively well preserved when parts of the model are destroyed or overloaded. More importantly, since representations are coded in patterns rather than firings of individual units, relationships between representations are coded in the similarities and differences between these patterns. So the internal properties of the representation carry information on what it is about (Clark 1993, p. 19). In contrast, local representation is conventional. No intrinsic properties of the representation (a unit's firing) determine its relationships to the other symbols. This self-reporting feature of distributed representations promises to resolve a philosophical conundrum about meaning. In a symbolic representational scheme, all representations are composed out of symbolic atoms (like words in a language). Meanings of complex symbol strings may be defined by the way they are built up out of their constituents, but what fixes the meanings of the atoms?

Connectionist representational schemes provide an end run around the puzzle by simply dispensing with atoms. Every distributed representation is a pattern of activity across all the units, so there is no principled way to distinguish between simple and complex representations. To be sure, representations are

composed out of the activities of the individual units. But none of these "atoms" codes for any symbol. The representations are sub-symbolic in the sense that analysis into their components leaves the symbolic level behind.

The sub-symbolic nature of distributed representation provides a novel way to conceive of information processing in the brain. If we model the activity of each neuron with a number, then the activity of the whole brain can be given by a giant vector (or list) of numbers, one for each neuron. Both the brain's input from sensory systems and its output to individual muscle neurons can also be treated as vectors of the same kind. So the brain amounts to a vector processor, and the problem of psychology is transformed into questions about which operations on vectors account for the different aspects of human cognition.

Sub-symbolic representation has interesting implications for the classical hypothesis that the brain must contain symbolic representations that are similar to sentences of a language. This idea, often referred to as the language of thought (or LOT) thesis may be challenged by the nature of connectionist representations. It is not easy to say exactly what the LOT thesis amounts to, but van Gelder (1990) offers an influential and widely accepted benchmark for determining when the brain should be said to contain sentence-like representations. It is that when a representation is tokened one thereby tokens the constituents of that representation. For example, if I write 'John loves Mary' I have thereby written the sentence's constituents: 'John' 'loves' and 'Mary'. Distributed representations for complex ideas like 'John loves Mary' can be constructed that do not contain any explicit representation of their parts (Smolensky 1991). The information about the constituents can be extracted from the representations, but neural network models do not need to explicitly extract this information themselves in order to process it correctly (Chalmers, 1990). This suggests that neural network models serve as counterexamples to the idea that the language of thought is a prerequisite for human cognition. However, the matter is still a topic of lively debate (Fodor, 1997).

The Shape of the Controversy between Connectionists and Classicists

The last thirty years have been dominated by the classical view that (at least higher) human cognition is analogous to symbolic computation in digital computers. On the classical account, information is represented by strings of symbols, just as we represent data in computer memory or on pieces of paper. The connectionist claims, on the other hand, that information is stored non-symbolically in the weights, or connection strengths, between the units of a neural net. The classicist believes that cognition resembles digital processing, where strings are produced in sequence according to the instructions of a (symbolic) program. The connectionist views mental processing as the dynamic and graded evolution of activity in a neural net, each unit's activation depending on the connection strengths and activity of its neighbors, according to the activation function.

On the face of it, these views seem very different. However many connectionists do not view their work as a challenge to classicism and some overtly support the classical picture. So-called implementational

connectionists seek an accommodation between the two paradigms. They hold that the brain's net implements a symbolic processor. True, the mind is a neural net; but it is also a symbolic processor at a higher and more abstract level of description. So the role for connectionist research according to the implementationalist is to discover how the machinery needed for symbolic processing can be forged from neural network materials, so that classical processing can be reduced to the neural network account.

However, many connectionists resist the implementational point of view. Such radical connectionists claim that symbolic processing was a bad guess about how the mind works. They complain that classical theory does a poor job of explaining graceful degradation of function, holistic representation of data, spontaneous generalization, appreciation of context, and many other features of human intelligence which are captured in their models. The failure of classical programming to match the flexibility and efficiency of human cognition is by their lights a symptom of the need for a new paradigm in cognitive science. So radical connectionists would eliminate symbolic processing from cognitive science forever.

The Systematicity Debate

The major points of controversy in the philosophical literature on connectionism have to do with whether connectionists provide a viable and novel paradigm for understanding the mind. One complaint is that connectionist models are only good at processing associations. But such tasks as language and reasoning cannot be accomplished by associative methods alone and so connectionists are unlikely to match the performance of classical models at explaining these higher-level cognitive abilities. However, it is a simple matter to prove that neural networks can do anything that symbolic processors can do since nets can be constructed that mimic a computer's circuits. So the objection can not be that connectionist models do not account for higher cognition; it is rather that they can do so only if they implement the classicist's symbolic processing tools. Implementational connectionism may succeed, but radical connectionists will never be able to account for the mind.

Fodor and Pylyshyn's often cited paper (1988) launches a debate of this kind. They identify a feature of human intelligence called systematicity which they feel connectionists cannot explain. The systematicity of language refers to the fact that the ability to produce/understand some sentences is intrinsically connected to the ability to produce/understand others of related structure. For example, no one with a command of English who understands 'John loves Mary' can fail to understand 'Mary loves John'. From the classical point of view, the connection between these two abilities can easily be explained by assuming that masters of English represent the constituents ('John', 'loves' and 'Mary') of , 'John loves Mary' and computes its meaning from the meanings of these constituents. If this is so, then understanding a novel sentence like 'Mary loves John' can be accounted for as another instance of the same symbolic process. In a similar way, symbolic processing would account for the systematicity of reasoning, learning and thought. It would explain why there are no people who are capable of concluding P from P&(Q&R), but incapable of concluding P from P&Q, why there are no people capable of learning to prefer red cube to green square who cannot learn to prefer a green cube to the red square, and why there isn't anyone who can think that John loves Mary who can't also think that Mary loves John.

Fodor and McLaughlin (1990) argue in detail that connectionists do not account for systematicity. Although connectionist models can be trained to be systematic, they can also be trained, for example, to recognize ‘John loves Mary’ without being able to recognize ‘Mary loves John’. Since connectionism does not guarantee systematicity, it does not explain why systematicity is found so pervasively in human cognition. Systematicity may exist in connectionist architectures, but where it exists, it is no more than a lucky accident. The classical solution is much better, because in classical models, pervasive systematicity comes for free.

The charge that connectionist nets cannot explain systematicity is initially quite plausible. However, careful analysis of the content of the claim is needed (Hadley, 1994). Furthermore, the view has been criticized lately by Aizawa (to appear), Garson (to appear), and Wallis, (to appear). One point common to these rebuttals is that symbolic processing models have exactly the same feature which was supposed to deny connectionists an ability to explain systematicity, for there are also classical models that can be programmed to accept ‘John loves Mary’ and reject ‘Mary loves John’.

Connectionism and the Elimination of Folk Psychology

Another important application of connectionist research to philosophical debate about the mind concerns the status of folk psychology. Folk psychology is the conceptual structure that we spontaneously apply to understanding and predicting human behavior. For example, knowing that John desires a beer and that he believes that there is one in the refrigerator allows us to explain why John just went into the kitchen. Such knowledge depends crucially on our ability to conceive of others as having desires and goals, plans for satisfying them, and beliefs to guide those plans. The idea that people have beliefs, plans and desires is a commonplace of ordinary life; but does it provide a faithful description of what is actually to be found in the brain?

Its defenders will argue that folk psychology is too good to be false (Fodor, 1988, Ch1). What more can we ask for the truth of a theory than that it provides an indispensable framework for successful negotiations with others? On the other hand, eliminativists will respond that the useful and widespread use of a conceptual scheme does not argue for its truth (Churchland 1989, Ch. 1). Ancient astronomers found the notion of celestial spheres useful (even essential) to the conduct of their discipline, but now we know that there are no celestial spheres. From the eliminativists point of view, an allegiance to folk psychology, like allegiance to folk (Aristotelian) physics, stands in the way of scientific progress. A viable psychology may require as radical a revolution in its conceptual foundations as is found in quantum mechanics.

Eliminativists are interested in connectionism because it promises to provide a conceptual foundation that would replace folk psychology. Simple cognitive tasks can be performed by neural networks that do not appear to contain any structures that could correspond to beliefs, desires and plans (Ramsey et. al., 1991). It is still an open question as to whether the complexities of human cognition can ever be captured by

such connectionist models. Furthermore, the whole issue of exactly what evidence about the brain would support the view that beliefs and desires are actively involved in the brain's processing is a cloudy one. The question is complicated further by disagreements about the nature of folk psychology. Many philosophers treat the beliefs and desires postulated by folk psychology as brain states with symbolic contents. For example, the belief that there is a beer in the refrigerator is thought to be a brain state that contains symbols corresponding to beer and a refrigerator. From this point of view, the fate of folk psychology is strongly tied to the symbolic processing hypothesis. On the other hand, some philosophers do not think folk psychology is essentially symbolic, and some would even challenge the idea that folk psychology is to be treated as a scientific theory in the first place. Under this conception, it is much more difficult to forge links between results in connectionist research and the rejection of folk psychology.

Mental Representation

If a representation is an object with semantic properties, then a mental representation is a mental object with semantic properties. According to the Representational Theory of Mind (RTM), psychological states are to be understood as relations between agents and mental representations: for an agent to be in a psychological state Ψ with semantic property Φ is for that agent to be in a Ψ-appropriate relation to a mental representation of an appropriate kind with semantic property Φ.

Historically, RTM (which goes back at least to Aristotle) is a theory of commonsense psychological states, such as belief, desire (the *propositional attitudes*), and perception. According to RTM, to *believe that p*, for example, is, in part, to bear the belief-relation (whatever that may be) to a mental representation that *means that p*. To perceive that *a* is Φ is, in part (propositional attitudes may also be involved), to have a sensory experience of some kind which is appropriately related (however that may be) to *a*'s being Φ.

The leading contemporary version of RTM, the Computational Theory of Mind (CTM), makes the further claims that the brain is a kind of computer and that mental processes are computations on mental representations. According to CTM, cognitive states are constituted by *computational* relations to mental representations of various kinds, and cognitive processes are rule-governed sequences of such states.

CTM develops RTM by attempting to explain *all* psychological states and processes in terms of mental representation. In the course of constructing detailed empirical theories of human and animal cognition and developing models of cognitive processes implementable in artificial information processing systems, cognitive scientists have proposed a variety of types mental representations. While some of these may be suited to be mental relata of commonsense psychological states, some -- so-called "subpersonal" or "sub-doxastic" representations -- are not. Though many philosophers believe that CTM stands to provide the best scientific explanations of cognition and behavior, there is disagreement over whether or not such explanations will vindicate the commonsense psychological explanations (and representations) of prescientific RTM.

Mental representation has also been of interest to philosophers who hold that the semantic properties of expressions of natural language (and many non-linguistic symbols as well) are inherited from the mental states of their users. For these theorists, RTM is a component of a complete theory of linguistic meaning.

Propositional Attitudes

Intentional Realists such as Dretske (1988) and Fodor (1987) argue that explanations and predictions of human behavior must quantify over inner states that are both causally efficacious and contentful, and have their causal powers (their causal roles) in virtue of having the content they do (i.e., the generalizations that describe the interaction of such states apply to them in virtue of their content: the desire that *q* and the belief that not *q* unless *q* cause (*ceteris paribus*) the desire that *q*, for example, because they are the desire that *q* and the belief that not *q* unless *p*). The generalizations we apply in everyday life in explaining others' behavior (often collectively referred to as "folk psychology") are both remarkably successful and indispensable. What a person believes, doubts, desires, fears, etc. is a highly reliable indicator of what he will do; and we have no other way of making sense of his behavior than by ascribing such states to him and applying the relevant generalizations. We are thus committed to the generalizations of commonsense psychology and, hence, to the existence of the states they quantify over. Such states, the *propositional attitudes*, are individuated by their contents and their characteristic psychological roles: they are relations to mental representations. Some realists (such as Fodor) also hold that commonsense psychology will be vindicated by cognitive science, given that propositional attitudes can be construed as *computational* relations to mental representations.

Intentional Eliminativists, such as Churchland, Stich and (perhaps) Dennett argue that no such things as propositional attitudes (and their implicated representational states) are necessary to the explanation of our mental lives and behavior.

Churchland denies that the generalizations of commonsense propositional-attitude psychology are true. He (1981) argues that folk psychology is a *theory* of the mind with a long history of failure and decline, and that it resists incorporation into the framework of modern scientific theories (including cognitive psychology). As such, it is comparable to alchemy and phlogiston theory, and ought to suffer a comparable fate. Commonsense psychology is *false*, and the states (and representations) it quantifies over simply don't exist. (It should be noted that Churchland is not an eliminativist about representation *tout court*. See, e.g., Churchland 1989.)

Dennett (1987a) grants that the generalizations of commonsense psychology are true and indispensable, but denies that this is sufficient reason to believe in the entities they seem to quantify over. He argues that to give an intentional explanation of a system's behavior is merely to adopt the "intentional stance" toward it. If the strategy of assigning contentful states to a system and predicting and explaining its behavior (on the assumption that it is *rational* -- i.e., that it behaves as it should, given the propositional attitudes it should have in its environment) is successful, then the system is intentional, and the propositional-attitude generalizations we apply to it are true. But there is nothing more to having a propositional attitude than this. (See Dennett 1987a: 29.)

Though he has been taken to be thus claiming that intentional explanations should be construed *instrumentally*, Dennett (1991) insists that he is a "moderate" realist about propositional attitudes, since he believes that the patterns in the behavior and behavioral dispositions of a system on the basis of which we (truly) attribute intentional states to it are objectively real. In the event, however, that there are two or more explanatorily adequate but substantially different systems of intentional ascriptions to an individual, Dennett claims, there is no fact of the matter about what the system believes (1987b, 1991). This does suggest an irrealism at least with respect to the sorts of things Fodor and Dretske take beliefs to be, though it is not the view that there is simply *nothing* in the world that makes intentional explanations true.

(Davidson (1973, 1974) and Lewis (1974) also defend the view that what it is to have a propositional attitude is just to be interpretable in a particular way. It is, however, not completely clear whether they intend their views to imply irrealism about propositional attitudes.)

Stich (1983) argues that cognitive psychology does not (or, in any case, *should* not) taxonomize mental states by their semantic properties at all. The generalizations of a scientific psychology will not quantify over representational states *qua* representational, and commonsense psychology will not be vindicated by CTM (properly understood). Attribution of psychological states by content is, Stich believes, sensitive to factors that render it problematic in the context of a scientific psychology -- viz., relations between an organism and its environment, and relations among psychological states.

Cognitive psychology seeks systematic *causal* explanations of behavior and cognition, and the causal powers of a mental state are determined by its *intrinsic* "structural" or "syntactic" properties (Stich calls this "the principle of psychological autonomy." See Stich 1978.) The semantic properties of a mental state (paradigmatically, its *reference*), in contrast, are determined by *extrinsic* properties -- viz., its history and environmental relations. Thus, such properties cannot figure in causal explanations of behavior.

Moreover, to ascribe a psychological state to an individual *by content* is (roughly) to say that the individual is in a state content-identical to the sort of state that typically causes one's own utterances of the sentence appearing in the content clause of the attribution. But the appropriateness of such ascriptions depends on what *other* psychological states the ascribee is (or is disposed to be) in. Since attribution by content is thus *holistic*, content-based psychological explanation of subjects who differ substantially from the ascriber(s) in their total system of beliefs is precluded (the generalizations will not apply).

Finally, ascription of a psychological state by content is sensitive to what other states an individual is

disposed to be in *as a result of* being in that state (in particular, what *inferences* the subject is disposed to make). But this renders content-based theories unable to make sense of subjects whose states have inference potential substantially different from those of the theorist. (Stich makes these last two points using examples of individuals whose psychology is, from the point of view of the ascriber, *pathological*.)

Stich also rejects, for essentially the reasons just enumerated, what he calls the Weak Representational Theory of Mind, on which psychological states have content but psychological generalizations do not apply to them in virtue of it. He argues for a *syntactic* theory of the mind, on which the semantic properties of mental states play *no* explanatory role: only the syntactic properties of mental states are relevant to their computational profiles.

Computation and Cognition

According to Stich's Syntactic Theory of the Mind, computational theories of psychological states should concern themselves only with the *formal* properties of the objects those states are relations to. Commitment to the explanatory relevance of *content*, however, is for most cognitive scientists fundamental (Fodor 1981a, Pylyshyn 1984, Von Eckardt 1993). That mental processes are computations, that computations are rule-governed sequences *of semantically evaluable objects* (*symbols*), and that the rules apply to the symbols in virtue of their content, are central tenets of mainstream cognitive science.

Explanations in cognitive science appeal to a variety of types of mental representation, including, for example, the "mental models" of Johnson-Laird 1983, the "retinal arrays," "primal sketches" and "2½ -D sketches" of Marr 1982, the "sub-symbolic" structures of Smolensky 1989, the "quasi-pictures" of Kosslyn 1980, and the "interpreted symbol-filled arrays" of Tye 1991 -- in addition to representations that may be appropriate to the explanation of commonsense psychological states. Computational explanations have been offered of, among other mental phenomena, belief (Fodor 1975, Field 1978), visual perception (Marr 1982, Osherson, et al. 1990), rationality (Newell and Simon 1972, Fodor 1975, Johnson-Laird and Wason 1977), language learning and use (Chomsky 1965, Pinker 1989), and musical comprehension (Lerdahl and Jackendoff 1983).

There is, however, disagreement among proponents of CTM as to what kinds of representations the brain uses, what kinds of neural structures realize them, and what kinds of brain-processes realize computations -- in short, on what *kind* of computer the brain is. The central debate here is between proponents of *Classical Architectures* and proponents of *Connectionist Architectures*.

The Classicists (e.g., Turing 1950, Fodor 1975, Newell and Simon 1976, Marr 1982, Fodor and Pylyshyn 1988) hold that mental representations are symbolic structures, which typically have semantically evaluable constituents, and mental processes are rule-governed manipulations of them. The Connectionists (e.g., McCulloch and Pitts 1943, Rumelhart and McClelland 1986, Rumelhart 1989, Smolensky 1988) hold that mental representations are realized by patterns of activation in a network of simple processors ("nodes") and mental processes consist of the spreading activation of such patterns. The nodes themselves are, typically, not taken to be semantically evaluable; nor do the patterns have

semantically evaluable constituents. (Though there are versions of Connectionism -- "localist" versions -- on which individual nodes are taken to have semantic properties (Ballard 1986, Ballard and Hayes, 1984). It is arguable, however, that localist theories are neither definitive nor representative of the connectionist program (Smolensky 1988, 1991; Chalmers 1993).)

The Classicists are motivated (in part) by properties thought seems to share with language. Fodor's Language of Thought Hypothesis (LOTH) (Fodor 1975, 1987), according to which the system of mental symbols constituting the neural basis of thought is taken to be structured like a symbolic language, provides a well-worked-out version of the Classical approach as applied to commonsense psychology. (Cf. also Marr 1982 for an application of classical approach in scientific psychology.) According to the LOTH, the potential infinity of complex representational mental states isgenerated from a finite stock of primitive representational states, combined in accordance with recursive rules. This combinatorial structure accounts for the properties of *productivity* and *systematicity* of the system of mental representation. A representational system is productive if there are indefinitely many distinct representations that may be constructed in it; it is systematic if the constructability of some representations is intrinsically connected to the constructability of others. As in the case of symbolic languages, including natural languages (though Fodor does not suppose either that the LOTH explains only linguistic capacities or that only verbal creatures have this sort of cognitive architecture), these properties of thought are explained by appeal to the independent contentfulness of the representational units and their combinability into contentful complexes. That is, the semantics of both language and thought is *compositional*: the content of a complex representation is determined by the contents of its constituents and their structural configuration.

The Connectionists are motivated mainly by a consideration of the architecture of the brain, which apparently consists of layered networks of interconnected neurons. They argue that this sort of architecture is unsuited to carrying out classical serial computations. For one thing, processing in the brain is typically massively parallel. In addition, the elements whose manipulation drives computation in connectionist networks (principally, the connections between nodes) are neither semantically compositional nor semantically evaluable, as they are on the classical approach. This contrast with classical computationalism is often characterized by saying that representation is, with respect to computation, *distributed* as opposed to *local*: representation is local if it is computationally basic; and distributed if it is not. (Another way of putting this is to say that for the Classicist mental representations are computationally *atomic*, whereas for the Connectionist they are not.)

Moreover, connectionists argue that information processing as it occurs in connectionist networks more closely resembles actual human cognitive functioning. For example, whereas on the classical view learning involves something like hypothesis formation and testing (Fodor 1981c), on the connectionist model it is a matter of evolving distribution of weights on the connections between nodes, and typically does not involve the representation of identity conditions for the objects of knowledge. The connectionist network is "trained up" by repeated exposure to objects it is to learn to distinguish; and this seems to model at least one type of human learning quite well. Further, degradation in the performance of such networks in response to damage is a gradual, not sudden as in the case of a classical information processor, and hence more accurately models the loss of human cognitive function as it typically occurs in

response to brain damage. It is also sometimes claimed that connectionist systems show the kind of flexibility in response to novel situations typical of human cognition -- situations in which classical systems are relatively "brittle" or "fragile."

Some philosophers have maintained that Connectionism entails irrealism about propositional attitudes. Ramsey, Stich and Garon (1990) have argued that if Connectionist models of cognition are basically correct, then there are no discrete representational states as conceived in ordinary commonsense psychology and classical cognitive science. Others, however (e.g., Smolensky 1989), hold that certain types of higher-level patterns of activity in a neural network may be roughly identified with the representational states of commonsense psychology. Still others (e.g., Fodor and Pylyshyn 1988, Heil 1991, Horgan and Tienson 1996) argue that language-of-thought style representation is both necessary in general and realizable within connectionist architectures. (MacDonald and MacDonald 1995 collects the central contemporary papers in the Classicist/Connectionist debate, and provides useful introductory material as well. See also Von Eckardt forthcoming.)

Whereas Stich (1983) accepts that mental processes are computational, but denies that computations are sequences of mental representations, others accept the notion of mental representation, but deny that CTM provides the correct account of mental states and processes.

Van Gelder (1995), for example, denies that psychological processes are computational. He argues that cognitive systems are *dynamic*, and that cognitive states are not relations to mental *symbols*, but quantifiable states of a complex system consisting of (in the case of human beings) a nervous system, a body and the environment in which they are embedded. Cognitive processes are not rule-governed sequences of discrete symbolic states, but continuous, evolving total states of dynamic systems determined by continuous, simultaneous and mutually determining states of the systems' components. Representation in a dynamic system is essentially information-theoretic; though the bearers of information are not symbols, but state variables or parameters. (See also Port and Van Gelder 1995.)

Horst (1996), on the other hand, argues that though computational models may be useful in scientific psychology, they are of no help in achieving a philosophical understanding of the intentionality of commonsense mental states. CTM attempts to *reduce* the intentionality of such states to the intentionality of the mental symbols they are relations to. But, he claims, the relevant notion of symbolic content is essentially bound up with the notions of convention and intention. So CTM involves itself in a vicious circularity: the very properties that are supposed to be reduced are (tacitly) appealed to in the reduction.

Content Determination

Another important issue for proponents of RTM is how mental representations *come to have* their semantic properties. There are two basic types of theory of content determination, *informational* theories and *functional* theories. Though theories of these types were designed to account for the content of commonsense psychological states, they may, at least in broad outline, serve as theories of content determination for sub-personal representational states as well.

Informational theories (Dretske 1981, 1988) hold that the content of a mental representation is grounded in the information it carries about what does (Devitt 1996) or would (Fodor 1987, 1990) cause its tokening. (Roughly, a state S of an object O carries the information that an object O* is in state S* iff it O*'s being in S* *reliably causes* O to be in S.) Informational theorists agree that information alone is not sufficient for the kind of content appropriate to commonsense psychological states such as belief, though they disagree on what additional properties an informational state must have in order to be a representation of the appropriate kind. Information is taken to be insufficient for two reasons. First, there are objects whose states carry information about states of affairs (for example, ringing telephones, tree trunks and speedometers) which they cannot be said to represent in the sense relevant to psychological states. Second, there is the infamous "Disjunction Problem," which reveals that bare informational theories are unable to account for the fact that causal relations hold between mental/neural states and states of affairs they do *not* represent -- i.e., the fact that we can think *false* thoughts.

The main attempts to solve the Disjunction Problem are the *Asymmetric Dependency Theory* (Fodor 1987, 1990a, 1994) and the *Teleological Theory* (Fodor 1990b, Millikan 1984, Papineau 1987, Dretske 1988, 1994). According to the Asymmetric Dependency Theory, the causal relation that determines content is the one without which the others would not hold, but which would itself hold even if the others did not. For example, since we would not (or would not be disposed to) token a mental representation of a horse when confronted with a zebra (say, in non-optimal perceptual conditions) if we did not (or were not disposed to) token a mental representation of a horse when confronted with a horse, but not vice versa, the mental representation tokened in the presence of horses means *horse*, in spite of the fact that there is a causal(informational) relation between it and zebras.

According to the Teleological Theory, the relation that determines content is the one the representation-producing mechanism has the *selected* (by evolution or learning) *function* of subserving. (For example, zebra-caused horse-representations do not mean *zebra*, because the mechanism by which those tokens were produced has the selected function of indicating horses, not zebras. The horse-representation-producing mechanism that responds to zebras is *malfunctioning*.)

Functional theories (Harman 1973, Block 1986) hold that the content of a mental representation is grounded in its (causal, computational, inferential) relations to other mental representations. They differ on whether relata should include all other mental representations or only some of them, and on whether to include external states of affairs. The view that the content of a mental representation is determined by its inferential/computational relations with *all* other representations is *holism*; the view it is determined by relations to only *some* other mental states is *localism* (or *molecularism*). (The view that the content of a mental state depends on *none* of its relations to other mental states is *atomism*.) Functional theories which recognize no content-constitutive external relata have been called *solipsistic* (Harman 1987). Some theorists posit distinct roles for internal and external connections, the former determining semantic properties analogous to sense, the latter determining semantic properties analogous to reference (Sterelny 1989).

Internalism and Externalism

Generally, those who, like informational theorists, think relations to one's (natural or social) environment are at least partially determinative of the content of one's mental representations are *externalists* (e.g., Putnam 1975, Burge 1979, 1986), whereas those who, like some proponents of functional theories, think representational content is determined by intrinsic properties alone, are *internalists* (or *individualists*; cf. Putnam 1975, Fodor 1981b).

This issue is of central importance, since the explanations of cognitive science are causal (computational), and the representational states these explanations quantify over are supposed to be subsumed under psychological generalizations in virtue of their content. If, however (as stressed by Stich), a mental representation's having a particular content is due to factors *extrinsic* to it, it is unclear how its having that content could determine its causal powers, which, arguably, must be intrinsic (Stich 1983; see also Fodor, 1982, 1987, 1994). Some who accept the Putnam and Burge arguments for externalism have argued that internal factors determine a *component* of the content of a mental representation. They say that mental representations have both "narrow" content (determined by intrinsic factors) and "wide" content (determined by narrow content plus extrinsic factors). (The distinction may as well be applied to the sub-personal representations of cognitive science as to those of commonsense psychology. See Von Eckardt 1993: 189.)

Narrow content has been variously construed. Putnam (1975), Fodor (1982: 114; 1994: 39ff), and Block (1986: 627ff), for example, seem to understand it as something like *de dicto* content (i.e.,Fregean *sense*, or perhaps *character* à la Kaplan 1989). On this construal, narrow content is metaphysically context-independent and directly expressible. Fodor (1987) and Block (1986), however, have also characterized narrow content as metaphysically context-independent but radically *inexpressible*. On this construal, narrow content is a kind of proto-content, or content-determinant, and can be specified only indirectly, via specifications of context/wide-content pairings. On both construals, narrow contents are characterized as functions from context to (wide) content. The narrow content of a representation is determined by properties intrinsic to it or its possessor -- its syntactic structure or its intramental computational or inferential role, for example.

Fodor (1994, 1998) has more recently urged that cognitive science might not need narrow mental representations in order to supply naturalistic (causal) explanations of human cognition and action, since the sorts of cases they were introduced to handle, viz., Twin-Earth cases and Frege cases, are either nomologically impossible or dismissible as exceptions to non-strict psychological laws.

Phenomenal and Non-phenomenal Representation

It is a common (though by no means unchallenged -- see below) assumption among realists about mental representations -- at least those of the sort appropriate to commonsense psychological states -- that they come in two basic varieties (cf. Boghossian 1995), with, correspondingly, two different kinds of

representational content. There are those -- for example percepts, sensory experiences and (perhaps) images -- which have phenomenal properties, and there are those -- for example concepts and thoughts -- which do not. Those of the former type maybe said to have *non-phenomenal content*, those of the latter type, *phenomenal content*. On this taxonomy, mental representations may represent in the way expressions of natural languages do, but they may also represent in a way drawings, paintings or photographs do -- i.e., by *resembling* what they represent. (An analogous distinction may also be available for the sub-personal representations proposed by cognitive scientists.)

Disagreement over phenomenal representation concerns the existence and nature of phenomenal properties (Dennett 1988 argues that there simply *are* no such things as qualia as ordinarily conceived), and the role they play (if they exist) in determining the content of sensory, perceptual, and imagistic representations. If a *sensation* is the mere having of a qualitative experience (a *quale*: a pain or tickle, an experience of blue or smoothness), while *perception* is sensory experience *of* something (in the external world), then, if perceptions are constituted in part by sensations -- that is, if they have sensory phenomenal properties -- a crucial question is what, if anything, such properties have to do with their representationalcontent.

Some historical discussions of the representational properties of the mind (e.g., Aristotle 1984, Locke 1978, Hume 1978) assumed that phenonmenal representations -- viz., percepts ("impressions") and images ("ideas") -- are the *only* kinds of mental representations, and that the mind represents the world in virtue of being in states that resemble it. On such a view, mental representations have their content in virtue of their introspectable phenomenal features. Powerful arguments, however, focusing on the lack of generality (Berkeley 1975), ambiguity (Wittgenstein 1953),and non-compositionality (Fodor 1981c) of perceptual and imagistic representations, as well as their unsuitability to function as logical (Frege 1918, Geach 1957) or mathematical (Frege 1953) concepts, and the symmetry of resemblance (Goodman 1976), convinced philosophers that no theory of the mind can get by with *only* imagistic representations. Some contemporary philosophers (Harman 1990, Leeds 1993, Rey 1991, Tye 1995, 2000) have argued that theories of the representational mind can get by with *no* phenomenal properties, since *symbolic* representations can do all the representational work of perception and imagination. (Block 1996 calls such philosophers "Representationists.")

Others (Evans 1982; Peacocke 1983, 1989, 1992; Raffman 1995; Shoemaker 1990) argue that a satisfactory theory of the representational mind *must* acknowledge phenomenal representations. (Block 1996 calls such philosophers "Phenomenists.") They claim that phenomenal properties are (at least partly) responsible for the representational powers of (at least) perceptual experiences (they do not claim that symbolic representation plays *no* role in determining the content of experience). Peacocke (1983, 1992), and Raffman (1995), for example, argue that we are capable of mentally representing perceivable properties of our environment that we do not (or cannot) represent symbolically.

Peacocke 1992 develops the notion of a perceptual "scenario" (an assignment of phenomenal properties to coordinates of a three-dimensional egocentric space), whose content is "correct" (a semantic property) if in the corresponding "scene" (the portion of the external world with the same origin and axes as the scenario) properties are distributed as they are in the scenario. He claims that such scenarios are possible

in the absence of symbolic representations corresponding to the properties represented. (Cf. the distinction in Dretske 1969 between epistemic and non-epistemic perception.)

Still others, including Chalmers 1996, Flanagan 1992, Goldman 1993, Jackendoff 1987, Levine 1993, 1995, McGinn 1992, Searle 1990 and Strawson 1995, claim that purely symbolic (conscious) representational states themselves have a proprietary phenomenology. If this claim is correct, the question of what, if anything, these properties have to do with content rearises for symbolic representation. (A Representationist answer could not be eliminativist with respect to phenomenal content if this claim is correct.)

Imagery

In a series of psychological experiments done in the 1970s (summarized in Kosslyn 1980 and Shepard and Cooper 1982), subjects' response time in tasks involving mental manipulation and examination of presented figures was found to vary in proportion to the spatial properties (size, orientation, etc.) of the figures presented. The question of how these experimental results are best explained has kindled a lively debate on the question of imagery.

Kosslyn claims that the results suggest that the tasks were accomplished via the examination and manipulation of mental representations that themselves have spatial properties -- i.e., *pictorial* representations, or *images*. Others, principally Pylyshyn (1979, 1981a, 1981b), argue that the empirical facts can be explained in terms exclusively of *discursive*, or *propositional* representations and cognitive processes defined over them. (Pylyshyn takes such representations to be sentences in a language of thought.)

The idea that pictorial representations are literally *pictures* in the head is not taken seriously by proponents of the pictorial view of imagery (see, e.g., Kosslyn and Pomerantz 1977). The claim is, rather, that mental images represent in a way that is relevantly *like* the way pictures represent. (Attention has been focused on *visual* imagery -- hence the designation ‘pictorial’; though of course there may imagery in other modalities -- auditory, olfactory, etc. -- as well.)

The distinction between pictorial and discursive representation can be characterized in terms of the distinction between *analog* and *digital* representation (Goodman 1976). This distinction has itself been variously understood (Fodor and Pylyshyn 1981, Goodman 1976, Haugeland 1981, Lewis 1971, McGinn 1989), though a widely accepted construal is that analog representation is continuous (i.e., in virtue of continuously variable properties of the representation), while digital representation is discrete (i.e., in virtue of properties a representation either has or doesn't have) (Dretske 1981). (An analog/digital distinction may also be made with respect to cognitive *processes*. (Block 1983.))

On this understanding of the analog/digital distinction, phenomenal representations, which represent in virtue of properties that may vary continuously (such as being more or less bright, loud, vivid, etc.), would be analog, while non-phenomenal representations, whose properties do not vary continuously (a

thought cannot be more or less about Paris: either it is or it is not) would be digital. It seems clear, however, that commitment to pictorial representation is not *ipso facto* commitment to *phenomenal* representation, since representations may have non-phenomenal properties that vary continuously.

There are, moreover, other ways of understanding pictorial representation that presuppose *neither* phenomenality nor analogicity.

Kosslyn, (1980, 1983), for example, uses the metaphor of a spatial display on a CRT screen to characterize pictorial representation: images are generated on a screen by a computer using information stored (in discursive form) in memory, and the spatial properties of the screen-image (which is composed of illuminated and unilluminated pixels) may correspond to the spatial properties of the imaged object. This isomorphism may be achieved without *literal* spatial representation in the brain. According to Kosslyn, a mental representation is "quasi-pictorial" when every part of the representation corresponds to a part of the object represented, and relative distances between parts of the object represented are preserved among the parts of the representation. Distances between two locations within a representation may be defined by number of intervening positions. (Kosslyn 1982.)

Moreover, intervention need not be *spatial*: it may, for example, be *functional*. That is, the distance between two points on an object might be represented by *computational* distance between the representations of the points -- if, for example, the number of computational steps required to *combine* stored information about the positions of the particular points equals (or is proportional to) the number of spatially intermediate points on the object represented. (Cf. Rey 1981.)

Tye (1991) proposes a view of images on which they are *hybrid* representations, consisting both of pictorial and discursive elements. On Tye's account, images are "(labeled) interpreted symbol-filled arrays." The symbols represent discursively, while their arrangement in arrays has representational significance (the location of each "cell" in the array represents a specific viewer-centered 2-D location on the surface of the imagined object).

Thought and Language

To say that a mental object has semantic properties is, paradigmatically, to say that it may be *about*, or be true or false of, an object or objects, or that it may be true or false *simpliciter*. Suppose I think that ocelots take snuff. I am thinking about ocelots, and if what I think of them (that they take snuff) is true of them, then my thought is true. According to RTM such states are to be explained as relations between agents and mental representations. To think that ocelots take snuff is to token in some way a mental representation whose content is that ocelots take snuff. On this view, the semantic properties of mental states are the semantic properties of the representations they are relations to.

Linguistic acts seem to share such properties with mental states. Suppose I *say* that ocelots take snuff. I am talking about ocelots, and if what I say of them (that they take snuff) is true of them, then my utterance is true. Now, to say that ocelots take snuff is (in part) to utter a sentence that means that ocelots

take snuff. Many philosophers have thought that the semantic properties of linguistic expressions are inherited from the mental states they are conventionally used to express (Grice 1957, Fodor 1978, Schiffer 1988, Searle 1983). On this view, the semantic properties of linguistic expressions are the semantic properties of the representations that are the mental relata of the states they are conventionally used to express.

(Others, however, e.g., Davidson (1975, 1982) have suggested that the kind of thought human beings are capable of is not possible without language, so that the dependency might be reversed, or somehow mutual (see also Sellars 1956). (But see Martin 1987 for a defense of the claim that thought is possible without language. See also Chisholm and Sellars 1958.) Schiffer (1987) subsequently despaired of the success of what he calls "Intention Based Semantics.")

It is also widely held that in addition to having such properties as reference, truth-conditions and truth -- so-called *extensional* properties -- expressions of natural languages also have *intensional* properties, in virtue of expressing properties or propositions -- i.e., in virtue of having *meanings* or *senses,* where two expressions may have the same reference, truth-conditions or truth value, yet express different properties or propositions (Frege 1892). So, if the semantic properties of natural-language expressions are inherited from the thoughts and concepts they express (or vice versa -- or both), then an analogous distinction may be appropriate for mental representations.

This distinction, which is accepted by many philosophers of mind, can be made out in a number of different ways (for example, the *de dicto*/*de re* interpretation of the narrow/wide distinction mentioned above). In general, theories of mental representation that accept a distinction between intrinsic and extrinsic determinants of content are called "two-factor" theories (Field 1978, Loar 1981, McGinn 1982). Such components may or may not be taken to be analogous to the intension and extension of a linguistic expression (Sterelny 1989).

Cognitive Science

Cognitive science is the interdisciplinary study of mind and intelligence, embracing philosophy, psychology, artificial intelligence, neuroscience, linguistics, and anthropology. Its intellectual origins are in the mid-1950s when researchers in several fields began to develop theories of mind based on complex representations and computational procedures. Its organizational origins are in the mid-1970s when the Cognitive Science Society was formed and the journal Cognitive Science began. Since then, more than sixty universities in North America and Europe have established cognitive science programs and many others have instituted courses in cognitive science.

History

Attempts to understand the mind and its operation go back at least to the Ancient Greeks, when philosophers such as Plato and Aristotle tried to explain the nature of human knowledge. The study of mind remained the province of philosophy until the nineteenth century, when experimental psychology developed. Wilhelm Wundt and his students initiated laboratory methods for studying mental operations more systematically. Within a few decades, however, experimental psychology became dominated by behaviorism, a view that virtually denied the existence of mind. According to behaviorists such as J. B. Watson, psychology should restrict itself to examining the relation between observable stimuli and observable behavioral responses. Talk of consciousness and mental representations was banished from respectable scientific discussion. Especially in North America, behaviorism dominated the psychological scene through the 1950s. Around 1956, the intellectual landscape began to change dramatically. George Miller summarized numerous studies which showed that the capacity of human thinking is limited, with short-term memory, for example, limited to around seven items. He proposed that memory limitations can be overcome by recoding information into chunks, mental representations that require mental procedures for encoding and decoding the information. At this time, primitive computers had been

around for only a few years, but pioneers such as John McCarthy, Marvin Minsky, Allen Newell, and Herbert Simon were founding the field of artificial intelligence. In addition, Noam Chomsky rejected behaviorist assumptions about language as a learned habit and proposed instead to explain language comprehension in terms of mental grammars consisting of rules. The six thinkers mentioned in this paragraph can be viewed as the founders of cognitive science.

Representation and Computation

The central hypothesis of cognitive science is that thinking can best be understood in terms of representational structures in the mind and computational procedures that operate on those structures. While there is much disagreement about the nature of the representations and computations that constitute thinking, the central hypothesis is general enough to encompass the current range of thinking in cognitive science, including connectionist theories which model thinking using artificial neural networks.

Most work in cognitive science assumes that the mind has mental representations analogous to computer data structures, and computational procedures similar to computational algorithms. Cognitive theorists have proposed that the mind contains such mental representations as logical propositions, rules, concepts, images, and analogies, and that it uses mental procedures such as deduction, search, matching, rotating, and retrieval. The dominant mind-computer analogy in cognitive science has taken on a novel twist from the use of another analog, the brain. Connectionists have proposed novel ideas about representation and computation that use neurons and their connections as inspirations for data structures, and neuron firing and spreading activation as inspirations for algorithms. Cognitive science then works with a complex 3-way analogy among the mind, the brain, and computers. Mind, brain, and computation can each be used to suggest new ideas about the others. There is no single computational model of mind, since different kinds of computers and programming approaches suggest different ways in which the mind might work. The computers that most of us work with today are serial processors, performing one instruction at a time, but the brain and some recently developed computers are parallel processors, capable of doing many operations at once.

Philosophical Relevance

Philosophy, in particular philosophy of mind, is part of cognitive science. But the interdisciplinary field of cognitive science is relevant to philosophy in several ways. First, the psychological, computational, and other results of cognitive science investigations have important potential applications to traditional philosophical problems in epistemology, metaphysics, and ethics. Second, cognitive science can serve as an object of philosophical critique, particularly concerning the central assumption that thinking is representational and computational. Third and more constructively, cognitive science can taken as an object of investigation in the philosophy of science, generating reflections on the methodology and presuppositions of the enterprise.

1. Philosophical Applications

Much philosophical research today is naturalistic, treating philosophical investigations as continuous with empirical work in fields such as psychology. From a naturalistic perspective, philosophy of mind is closely allied with theoretical and experimental work in cognitive science. Metaphysical conclusions about the nature of mind are to be reached, not by a priori speculation, but by informed reflection on scientific developments in fields such as computer science and neuroscience. Similarly, epistemology is not a stand-alone conceptual exercise, but depends on and benefits from scientific findings concerning mental structures and learning procedures. Even ethics can benefit by using greater understanding of the psychology of moral thinking to bear on ethical questions such as the nature of deliberations concerning right and wrong. Goldman (1993) provides a concise review of applications of cognitive science to epistemology, philosophy of science, philosophy of mind, metaphysics, and ethics.

2. Critique of Cognitive Science

The claim that human minds work by representation and computation is an empirical conjecture and might be wrong. Although the computational-representational approach to cognitive science has been successful in explaining many aspects of human problem solving, learning, and language use, some philosophical critics such as Hubert Dreyfus and John Searle have claimed that this approach is fundamentally mistaken. Critics of cognitive science have offered such challenges as:

- 1. The emotion challenge: Cognitive science neglects the important role of emotions in human thinking.
- 2. The consciousness challenge: Cognitive science ignores the importance of consciousness in human thinking.
- 3. The world challenge: Cognitive science disregards the significant role of physical environments in human thinking.
- 4. The social challenge: Human thought is inherently social in ways that cognitive science ignores.
- 5. The dynamical systems challenge: The mind is a dynamical system, not a computational system.
- 6. The mathematics challenge: Mathematical results show that human thinking cannot be computational in the standard sense, so the brain must operate differently, perhaps as a quantum computer.

Thagard (1996) argues that all these challenges can best be met by expanding and supplementing the computational-representational approach, not by abandoning it.

3. Philosophy of Cognitive Science

Cognitive science raises many interesting methodological questions that are worthy of investigation by

philosophers of science. What is the nature of representation? What role do computational models play in the development of cognitive theories? What is the relation among apparently competing accounts of mind involving symbolic processing, neural networks, and dynamical systems? Von Eckardt (1993) provides a good discussion of some of the philosophical issues that arise in cognitive science.

Consciousness and Intentionality

To say one has an experience that is conscious (in the phenomenal sense) is to say that one is in a state of its *seeming* to one some way. In another formulation, to say experience is conscious is to say that there is *something it's like* for one to have it. Feeling pain and sensing colors are common illustrations of phenomenally conscious states. Consciousness has also been taken to consist in the monitoring of one's own states of mind (e.g., by forming thoughts about them, or by somehow "sensing" them), or else in the accessability of information to one's capacities for rational control or self-report. Intentionality has to do with the directedness or aboutness of mental states -- the fact that, for example, one's thinking is *of* or *about* something. Intentionality includes, and is sometimes taken to be equivalent to, what is called ‘mental representation.’

It can seem that consciousness and intentionality pervade mental life -- perhaps one or both somehow constitute what it is to have a mind. But achieving an articulate general understanding of either consciousness or intentionality presents an enormous challenge, part of which lies in figuring out how the two are related. Is one in some sense derived from or dependent on the other? Or are they perhaps quite independent and separate aspects of mind?

Sections (1) and (2) offer introductory accounts of what is meant by ‘consciousness’ and ‘intentionality,’ with sensitivity to the difficulties raised by their varying interpretation. Then, influential perspectives on intentionality that have emerged in both phenomenological (Section 3) and analytic (Section 4) philosophical traditions are sketched, so as to highlight basic issues about the relationship of consciousness and intentionality, and provide some of the background against which they have been understood. Sections (5) through (8) survey some contemporary views about consciousness, considering their implications for the connection between consciousness and intentionality. Section (9) distinguishes four broad options for understanding their relationship, and closes with some observations about the philosophical consequences of choosing among them.

---

1. Consciousness: Different Senses (or Kinds)?

On one understanding frequent among philosophers, consciousness is a certain feature shared by sense-experience and imagery, perhaps belonging also to a broad range of other mental phenomena (e.g., episodic thought, memory, and emotion). It is the feature that consists in its *seeming* some way to one to have experiences. To put it another way: conscious states are states of its seeming somehow to a subject.

For example, it seems to you some way to see red, and seems to you (some other way) to hear a crash, to visualize a triangle, and to suffer pain. The sense of ‘seems’ relevant here may be brought out by noting that, in the last example, we might just as well speak of the way it *feels* to be in pain. And -- some will want to say -- in the same sense, it seems to you some way to think through the answer to a math problem, or to recall where you parked the car, or to feel anger, shame, or elation. (Note however, that it is not simply to be assumed that saying it seems some way to you to *have* an experience is equivalent to saying that the experience *itself* seems or appears some way to you -- that it is an object of appearance. The point is just that the way something sounds to you, the way something looks to you, etc., all constitute ‘ways of seeming.’) States that are conscious in this sense are said to have some *phenomenal character* or other -- their phenomenal character being the specific way it seems to one to have a given experience. Sometimes this is called the ‘qualitative’ or ‘subjective’ character of experience.

Another oft-used means for trying to get at the relevant notion of consciousness, preferable to some, is to say that there is, in a certain sense, always ‘something it is like’ to be in a given conscious state -- something it's like *for* one who is in that state. Relating the two locutions we might say: there is something it is like for you to see red, to feel pain, etc., and the way it seems to you to have one of these experiences *is* what it is like for you to have it. The phenomenal character of an experience then, is what someone would inquire about by asking, e.g., ‘What is it like to experience orgasm?’ -- and it is what we speak of when we say that we know *what that is like*, even if we cannot convey this to one who *doesn't* know. And, if we want to speak of *persons*, or other creatures (as distinct from their *states*) being conscious, we will say that they are conscious just if there is something it is like for them to be the creatures they are -- for example, something it is like to be a bat.

The examples of conscious states given comprise a various lot. But some sense of their putative unity as instances of consciousness might be gained by contrasting them with what we are inclined to exclude, or can at least conceive of excluding, from their company. Much of what goes on we would ordinarily

believe is not (or at any rate, we may well suppose is not) conscious in the sense at issue. The leaf's fall from a tree branch, we may suppose, is not a conscious state of the leaf -- a state of its seeming somehow to the leaf. Nor, for that matter, is a *person's* fall off a branch a conscious state of that person -- rather, it is the *feeling* of falling that is conscious, if anything is. *Dreaming* of falling would also be a conscious experience in this sense. But, while we can in some way be said to sense the position of our limbs even while dreamlessly asleep, we may still suppose that this proprioception (though perhaps in some sense a mental or cognitive affair) is not conscious -- we may suppose that it does not then seem (or feel) any way to us sleepers to sense our limbs, as ordinarily it does when we are awake.

The ‘way of seeming’ or ‘what it's like’ conception of consciousness I have just invoked is sometimes marked by the term ‘phenomenal consciousness.’ But this qualifier ‘phenomenal’ suggests that there are other kinds of consciousness (or perhaps, other *senses* of ‘consciousness’). Indeed there are, at least, other *ways of introducing* notions of consciousness. And these may appear to pick out features or senses altogether distinct from that just presented. For example, it is said that some (but not all) that goes on in the mind is ‘accessible to consciousness.’ Of course this by itself does not so much specify a sense of ‘conscious’ as put one in use. (One will want to ask: And just what is this ‘consciousness’ that has ‘access’ to some mental goings-on but not others, and what could ‘access’ mean here, anyway?) However, some have evidently thought that, rather than speak of consciousness as what *has* access, we should understand consciousness as itself a certain kind of susceptibility to access. For example, Daniel Dennett (1969) once theorized that one's conscious states are just those whose contents are available to one's direct verbal report -- or, at least, to the ‘speech center’ responsible for generating such reports. And Ned Block (1995) has proposed that, on one understanding of ‘conscious,’ (to be found at work in many ‘cognitive’ theories of consciousness) a conscious state is just a ‘representation poised for free use in reasoning and other direct ‘rational’ control of action and speech.’ Block labels consciousness in this sense ‘access consciousness.’

Block would insist that we should distinguish phenomenal consciousness from ‘access consciousness,’ and he argues that a mental representation's being poised for use in reasoning and rational control of action is neither a necessary nor a sufficient condition for the state's being *phenomenally* conscious. Similarly he distinguishes phenomenal consciousness from what he calls ‘reflexive consciousness’ -- where this has to do with one's capacity to represent one's mind's to oneself -- to have, for example, thoughts about one's own thoughts, feelings, or desires. Such a conception of consciousness finds some support in a tendency to say that conscious states of mind are those one is ‘conscious of’ or ‘aware of’ being in, and to interpret this ‘of’ to indicate some kind of reflexivity is involved -- wherein one represents one's own mental representations (Rosenthal 1986, 1991, 1993). On one prominent variant of this conception, consciousness is taken to be a kind of scanning or perceiving of one's own psychological states or processes -- an ‘inner sense’ (Armstrong 1968, Lycan 1996).

Block's threefold division of phenomenal, access, and reflexive consciousness need not be taken to reflect clear and coherent distinctions already contained in our pre-theoretical use of the term ‘conscious.’ Block himself seems to think that (on the contrary) our initial, ordinary use of ‘conscious’ is too confused even to count as ambiguous. Thus in articulating an interpretation, or set of interpretations, of the term adequate to frame theoretical issues, we cannot simply describe how it is currently employed -- we must

assign it a more definite and coherent meaning than extant in common usage (Block 1995).

Whether or not this is correct, getting a firm footing here is not easy, and a number of theorists of consciousness would balk at proceeding on the basis of Block's proposed threefold distinction. Sometimes the difficulty may be merely terminological. John Searle, for example, would recognize phenomenal consciousness, but deny Block's other two candidates are proper senses of ‘conscious’ at all (Searle 1995). The reality of some sort of access and reflexivity is apparently not at issue -- just whether either captures a senseof ‘conscious’ (perhaps confusedly) woven into our use of the term. However, in contrast to both Block and Searle, there are also those who raise doubts that there is a properly *phenomenal* sense we can apply, distinct from both of the other two, for us to pick out with *any* term (see Dennett 1988, 1991, Lycan 1996, and Rey 1997). This is not just a dispute about words, but about what there is for us to talk about with them.

The substantive issues here are very much bound up with differences over the proper way to conceive of the relationship between consciousness and intentionality. If there are distinct senses in which states of mind could correctly said to be ‘conscious’ (answering perhaps to something like Block's three-fold distinction), then there will be distinct questions we can pose about the relation between consciousness and intentionality. But if one of Block's alleged senses is somehow fatally confused, or if he is wrong to distinguish itfrom the others, or if it is the sense of *no* term we can with warrant apply to ourselves or our states, then there will be no separate question in which it figures we should try to answer. Thus, trying to work out a reasoned view about what we are (or should be) talking about when we talk about consciousness is an unavoidable and non-trivial part of trying to understand the relation between consciousness and intentionality.

To clarify further the disputes about consciousness and their links to questions about its relation to intentionality, we need to get an initial grasp of the relevant way the terms ‘intentionality’ and ‘intentional’ are used in philosophy of mind.

2. Intentionality: Directedness; Conditions of Satisfaction; Content

The previous section gives some indication of why it is difficult to get a theory of consciousness started. While the term ‘conscious’ is not esoteric, its use is not easily characterized or rendered consistent in a manner providing some uncontentious framework for theoretical discussion. Where the term ‘intentional’ is concerned, we also face initially confusing and contentious usage. But here the difficulty lies partly in the fact that the relevant use of cognate terms is simply *not* that found in common speech (as when we speak of doing something ‘intentionally’). Though ‘intentionality,’ in the sense here at issue, does seem to attach to some real and fundamental (maybe even defining) aspect of mental phenomena, the relevant use of the term is tangled up with some rather involved philosophical history.

One way of explaining what is meant by ‘intentionality’ in the (more obscure) philosophical sense is this:

it is that aspect of mental states or events that consists in their being *of* or *about* things (as pertains to the questions, ‘What are you thinking of?’ and ‘What are you thinking about?’). Intentionality is the *aboutness* or *directedness* of mind (or states of mind) to things, objects, states of affairs, events. So if you are thinking about San Francisco, or about the increased cost of living there, or about your meeting someone there at Union Square -- your mind, your thinking, is directed toward San Francisco, or the increased cost of living, or the meeting in Union Square. To think at all is to think of or about something in this sense. This ‘directedness’ conception of intentionality plays a prominent role in the influential philosophical writings of Franz Brentano and those whose views developed in response to his (to be discussed further in Section 3).

But what kind of ‘aboutness’ or ‘of-ness’ or ‘directedness’ is this, and to what sorts of things does it apply? How do the relevant ‘intentionality-marking’ senses of these words (‘about,’ ‘of,’ ‘directed’) differ from: the sense in which the cat is wandering ‘about’ the room; the sense in which someone is a person ‘of’ high integrity; the sense in which the river's course is ‘directed’ towards the fields?

It has been said that the peculiarity of this kind of directedness/aboutness/of-ness lies in its capacity to relate thought or experience to objects that (unlike San Francisco) do not exist. One can think about a meeting that has not, or never will occur; one can think of Shangri La, or El Dorado, or the New Jerusalem; one may think of their shining streets, of their total lack of poverty, or of their citizens' peculiar garb. Thoughts, unlike roads, can lead to a city that is not there.

But to talk in this way only invites new perplexities. Is this to say (with apparent incoherence) that there *are* cities that *do not exist*? And what does it mean to say that, when a state of mind is in fact ‘directed toward’ something that does exist, that state nevertheless *could* be directed toward something that does not exist? It can well seem to be something very fundamental to the nature of mind that our thoughts, or states of mind more generally, can be of or about things or ‘point beyond themselves.’ But a coherent and satisfactory theoretical grasp of this phenomenon of ‘mental pointing’ in all its generality is difficult to achieve.

Another way of trying to get a grip on the topic asks us to note that the potential for a mental directedness towards the non-existent is evidently closely associated with the mind's potential for falsehood, error, inaccuracy, illusion, hallucination, and dissatisfaction. What makes it possible to believe (or even just suppose) something about Shangri La is that one can falsely believe (or suppose) that something exists. In the case of perception, what makes it possible to seem to see or hear what is not there is that one's experience may in various ways be inaccurate, nonveridical, subject to illusion, or hallucinatory. And, what makes it possible for one's desires and intentions to be directed toward what does not and never will exist is that one's desires and intentions can be unfulfilled or unsatisfied. This suggests another strategy for getting a theoretical hold on intentionality, employing a notion of *satisfaction*, stretched to encompass susceptibility to each of these modes of assessment, each of these ways in which something can either go right, or go wrong (true/false, veridical/nonveridical, fulfilled/unfulfilled), and speak of intentionality in terms of having ‘conditions of satisfaction.’ On John Searle's (1983) conception, intentional states are those having conditions of satisfaction. What are conditions of satisfaction? In the case of belief, these are the conditions under which the belief is true; in the case of perception, they are the conditions under

which sense-experience is veridical; in the case of intention, the conditions under which an intention is fulfilled or carried out.

However, while the conditions of satisfaction approach to the notion of intentionality may furnish an alternative to introducing this notion by talking of ‘directedness to objects,’ it is not clear that it can get us around the problems posed by the ‘directedness’ talk. For instance, what are we to say where thoughts are expressed using names of nonexistent deities or fictional characters? Will we do away with a troublesome directedness to the nonexistent by saying that the thoughts that Zeus is Poseidon's brother, and that Hamlet is a prince, are just false? This is problematic. Moreover, how will we state the conditions of satisfaction of such thoughts? Will this not also involve an apparent *reference* to the nonexistent? (For discussion of these issues, see, for example, Thomasson 1999.)

A third important way of conceiving of intentionality, one particularly central to the analytic tradition derived from the study of Frege and Russell (see Section 4), asks us to focus on the notion of mental (or intentional) *content*. Often, it is assumed: to have intentionality is to have content. And frequently mental content is otherwise described as *representational* or *informational* content -- and ‘intentionality’ (at least, as this applies to the mind) is seen as just another word for what is called ‘mental representation,’ or a certain way of bearing or carrying information.

But what is meant by ‘content’ here? As a start we may note: the content of *thought*, in this sense, is what is reported when answering the question, ‘What does she think?’ by something of the form, ‘She thinks that *p*.’ And the content of thought is what two people are said to share, when they are said to think the same thought. (Similarly, the content of belief is what two people share when they hold the same belief.) Content is also what may be shared in this way even while ‘psychological modes’ of states of mind may differ. For example: *believing* that I'll soon be bald and *fearing* that I'll soon be bald share the content: *that I'll soon be bald*.

Also, commonly, content is taken as not only that which is *shared* in the ways illustrated, but that which *differs* in a way revealed by considering certain logical features of sentences we use to talk about states of mind. Notably: the constituents of the sentence that fills in for ‘*p*’ when we say ‘*x* thinks that *p*’ or ‘*x* believes that *p*’ are often interpreted in such a way that they display ‘failures of substitutivity’ of (ordinarily) co-referential or co-extensional expressions, and this appears to reflect differences in mental content. For example: if George W. Bush is the eldest son of the vice-president under Ronald Reagan, and George W. Bush is the current U.S. President, then it can be validly inferred that the eldest son of Reagan's vice-president is the current U.S. President. However, we cannot always make the same sort of substitutions of terms when we use them to report what someone *believes*. From the fact that you *believe* that George W. Bush is the current U.S. President, we cannot validly infer that you believe that the eldest son of Reagan's vice-president is the current U.S. President. That last may still be false, even if George W. Bush is indeed the eldest son. These logical features of the sentences ‘*x* believes that George W. Bush is the current U.S. President’ and ‘*x* believes that George W. Bush is the eldest son of Reagan's vice-president’ seem to reflect the fact that the *beliefs* reported by their use have different *contents*: these sentences are used by someone to state *what is believed* (the belief content), and what is believed in each case is not just the same. Someone's belief may have the one content without having the other.

Similar observations can be made for other intentional states and the reports made of them -- especially when these reports contain an object clause beginning with ‘that’ and followed by a complete sentence (e.g., she thinks that *p*; he intends that *p*; she hopes that *p*; he fears that *p*; she sees that *p*). Sometimes it is said that the content of the states is ‘given’ by such a ‘that *p*’ clause when ‘*p*’ is replaced by a sentence -- the so-called ‘content clause.’

This ‘possession of content’ conception of intentionality may be coordinated with the ‘conditions of satisfaction’ conception roughly as follows. If states of mind contrast in respect of their satisfaction (say, one is true and the other false), they differ in content. (One and the same belief content cannot be both true and false -- at least not in the same context at the same time.) And if one says what the intentional *content* of a state of mind is, one says much or perhaps all of what *conditions must be met* if it is to be satisfied -- what its conditions of truth, or veridicality, or fulfillment, are. But one should be alert to how the notion of content employed in a given philosopher's views is heavily shaped by these views, and one should note how commonly it is held that the notion of content is in this or that way ambiguous or in need of refinement. (Consider, for example: Jerry Fodor's (1991) defense of a distinction between ‘narrow’ and ‘wide’ content; Edward Zalta's (1988) distinction between ‘cognitive’ and ‘objective’ content; and John Perry's (2001) distinction between ‘reflexive'and ‘subject-matter’ content.)

It is arguable that each of these gates of entry into the topic of intentionality (directedness; conditions of satisfaction; mental content) opens onto a unitary phenomenon. But evidently there is also considerable fragmentation in the conceptions of both consciousness and intentionality that are in the field. To get a better grasp of some of the ways the relationship between consciousness and intentionality can be viewed, without begging questions or trying to present a positive theory on the topic, it is useful to take a look at the recent history of thinking about intentionality, in a way that will bring several issues about its relationship with consciousness to the fore. Together with the preceding discussion, this should provide the background necessary for examining some of the differences that divide those who theorize about consciousness that are very intimately involved with views of the consciousness-intentionality relation.

If we are to acknowledge the extent to which the notion of intentionality is the creature of philosophical history, we have to come to terms with the divide in twentieth century western philosophy between so-called ‘analytic’ and ‘continental’ philosophical traditions. Both have been significantly concerned with intentionality. But differences in approach, vocabulary, and background assumptions have made dialogue between them difficult. It is almost inevitable, in a brief exposition, to give largely independent summaries of the two. We will start with the ‘continental’ side of the story -- more, specifically, with the phenomenological movement in continental philosophy. However, while these traditions have developed without a great deal of intercommunication, they do have common sources, and have come to focus on issues concerning the relationship of consciousness and intentionality that are recognizably similar.

3. Brentano, Husserl, and the Phenomenological Movement

A thorough look at the historical roots of controversies over consciousness and intentionality would take us farther into the past than it is feasible to go in this article. A relatively recent, convenient starting point would be in the philosophy of Franz Brentano. He more than any other single thinker is responsible for keeping the term ‘intentional’ alive in philosophical discussions of the last century or so, with something like its current use, and was much concerned to understand its relationship with consciousness (Brentano [1874] 1973). However, it is worth noting that Brentano himself was very aware of the deep historical background to his notion of intentionality: he looked back through scholastic discussions (crucial to the development of Descartes' immensely influential theory of ideas), and ultimately to Aristotle for his theme of intentionality (Brentano [1867] 1977). One may well go further back, to Plato's discussion (in the *Sophist*, and the *Theaetetus*) of difficulties in making sense of false belief, and yet further still, to the dawn of Western Philosophy, and Parmenides' attempt to draw momentous consequences from his alleged finding that it is not possible to think or speak of what is not.

In Brentano's treatment what seems crucial to intentionality is the mind's capacity to ‘refer’ or be ‘directed’ to objects existing solely in the mind -- what he called ‘mental or intentional inexistence.’ It is subject to interpretation just what Brentano meant by speaking of an object existing only in the mind and not outside of it, and what he meant by saying that such ‘immanent’ objects of thought are not ‘real.’ He complained that critics had misunderstood him here, and also appears to have revised his position significantly as his thought developed. But it is clear at least that his conception of intentionality is dominated by the first strand in thought about intentionality mentioned above -- intentionality as ‘directedness towards an object’ -- and whatever difficulties that brings in train.

Brentano's conception of the relation between consciousness and intentionality can be brought out partly by noting he held that every conscious mental phenomenon is both directed towards an object, and always (if only ‘secondarily’) directed towards itself. (That is, it includes a ‘presentation’ -- and ‘inner perception’ -- of itself). Since Brentano also denied the existence of unconscious mental phenomena, this amounts to the view that all mental phenomena are, in a sense ‘self-presentational.’

His lectures in the late nineteenth century attracted a diverse group of central European intellectuals (including that great promoter of the *unconscious*, Sigmund Freud) and the problems raised by Brentano's views were taken up by a number of prominent philosophers of the era, including Edmund Husserl, Alexius Meinong, and Kasimir Twardowski. Of these, it was Husserl's treatment of the Brentanian theme of intentionality that was to have the widest philosophical influence on the European Continent in the twentieth century -- both by means of its transformation in the hands of other prominent thinkers who worked under the aegis of ‘phenomenology’ -- such as Martin Heidegger, Jean-Paul Sartre, and Maurice Merleau-Ponty -- and through its rejection by those embracing the ‘deconstructionism’ of Jacques Derrida.

In responding to Brentano, Husserl also adopted his concern with properly understanding the way in which thought and experience are “directed towards objects.” Husserl ([1900] 1970, [1928] 1966) criticized Brentano's doctrine of ‘inner perception,’ and did not deny (even if he did not affirm) the reality of unconscious mentation. But Husserl retained Brentano's primary focus on describing conscious ‘mental acts.’ Also he believed that knowledge of one's own mental acts rests on an ‘intuitive’ apprehension of

their instances, and held that one is, in some sense, conscious *of* each of one's conscious experiences (though he denied this meant that every conscious experience is an object of an intentional act). Evidently Husserl wished to deny that all conscious acts are objects of inner perception, while also affirming that *some* kind of reflexivity -- one that is, however, neither judgment-like nor sense-like -- is essentially built into every conscious act. But the details of the view are not easy to make out. (A similar (and similarly elusive) view was expressed by Jean-Paul Sartre in the doctrine that “every consciousness is a non-positional consciousness of itself”([1937] 1957, [1942] 1953).) (For recent discussion of Brentano and Husserl and of the relation between the two on these topics, see Thomasson 2000 and Zahavi 1998.)

One of Husserl's principal points of departure in his early treatment of intentionality (in the *Logical Investigations* [1900] 1970) was his criticism of (what he took to be) Brentano's notion of the ‘mental inexistence’ of the objects of thought and perception. Husserl thought it a fundamental error to suppose that the object (the ‘intentional object’) of a thought, judgment, desire, etc. is always an object ‘in’ (or ‘immanent to’) the mind of the thinker, judger, or desirer. The objects of one's ‘mental acts’ of thinking, judging, etc. are often objects that ‘transcend,’ and exist independently of these acts (states of mind) that are directed towards them (that ‘intend’ them, in Husserl's terms). This is particularly striking, Husserl thought, if we focus on the intentionality of sense perception. The object of my visual experience is not something ‘in my mind,’ whose existence depends on the experience -- but something that goes beyond or ‘transcends’ any (necessarily perspectival) experience I may have of it. This view is phenomenologically based, for (Husserl says), the object is *experienced as* perspectivally given, hence as ‘transcendent’ in this sense.

In cases of hallucination, we should say, on Husserl's view, not that there is an object existing ‘in one's mind,’ but that the object intended does not exist at all. This does not do away with the ‘directedness’ of the experience, for that is properly understood (according to the *Logical Investigations*) as its having a certain ‘matter’ -- where the matter of a mental act is what may be common to different acts, when, for example, one believes that it will not rain tomorrow, and hopes that it will not rain tomorrow. The difference between the mental acts illustrated (between hoping and believing) Husserl would term a difference in their ‘quality.’ Husserl was to re-interpret his notions of act-matter and quality as components of what he called (in *Ideas* [1913] 1983) the ‘noema’ or ‘noematic structure’ that can be common to distinct particular acts. So intentional directedness is understood not as a relation to special (mental) objects towards which one is directed, but rather: as the possession by mental acts of matter/quality (or later, ‘noematic’) structure.

This unites Husserl's discussion with the ‘content’ conception of intentionality described above: he himself would accept that the matter of an act (later, its ‘noematic sense’) is the same as the *content* of judgment, belief, desire, etc., in one sense of the term (or rather, in one sense he found in the ambiguous German ‘*gehalt*’). However, it is not fully clear how Husserl would view the relationship between either act-matter or noematic sense quite generally and such semantic correlates of ordinary language sentences that some would identify as the contents of states of mind reported in them. This is a difficulty partly because of his later emphasis (e.g., in *Experience and Judgment* [1928] 1972) on the importance of what he called ‘pre-predicative’ experience. He believed that the sort of judgments we express in ordinary and scientific language are ‘founded on’ the intentionality of pre-predicative experience, and that it is a central

task of philosophy to clarify the way in which such experience of our surroundings and our own bodies underlies judgment, and the capacity it affords us to construct an 'objective' conception of the world. Pre-predicative experience is, paradigmatically, sense experience as it is given to us, independently of any active judging or predication. But did Husserl hold that what makes such experience pre-predicative is that it altogether lacks the content that is expressed linguistically in predicative judgment, or did he think that such judgment merely *renders explicit* a predicative content that even 'pre-predicative' experience already (implicitly) has? Just what does the 'pre-' in 'pre-predicative' entail?

Perhaps this is not clear. In any case, the theme of a type of intentionality more fundamental than that involved in predicative judgments that 'posit' objects, and to be found in everyday experience of our surroundings, was taken up, in different ways, by later phenomenologists, Heidegger and Merleau-Ponty. The former describes a type of 'directed' 'comportment' towards beings in which they 'show themselves' as 'ready-to-hand,' (or, in Dreyfus' (1991) interpretation, as 'available'). Heidegger thinks this characterizes our ordinary practical involvement with our surroundings, and regards it as distinct from, and somehow providing a basis for, entities showing themselves to us as 'present-at-hand' (or 'occurrent') -- as they do when we take a less context-bound, more theoretical stance towards the world (Heidegger [1927] 1962). Later, Merleau-Ponty ([1949] 1962), influenced by his study of Gestalt psychology and neurological case studies describing pathologies of perception and action, held that normal perception involves a consciousness of place tied essentially to one's capacities for exploratory and goal-directed movement, which is indeterminate relative to attempts to express or characterize it in terms of 'objective' representations -- though it makes such an objective conception of the world possible.

Whether Heidegger's and Merleau-Ponty's moves in these directions actually contradict Husserl, they clearly go beyond what he says. Another basic, exegetically complex, apparent difference between Husserl and the two later philosophers, pertinent to the relationship of consciousness and intentionality, lies in the controversy over Husserl's proposed 'phenomenological reduction.' Husserl claimed it is possible (and, indeed, essential to the practice of phenomenology) that one conduct an investigation into the structure of consciousness that carefully abstains from affirming the existence of anything in spatio-temporal reality. By this 'bracketing' of the natural world, by reducing the scope of one's assertions first to the subjective sphere of consciousness, then to its abstract (or 'ideal') atemporal structure, one is able to apprehend what consciousness and its various forms essentially are, in a way that supplies a foundation to the philosophical study of knowledge, meaning and value. Both Heidegger and Merleau-Ponty (along with a number of Husserl's other students) appear to have questioned whether it is possible to reduce one's commitments as thoroughly as Husserl appears to have prescribed through a 'mass abstention' from judgment about the world, and thus whether it is correct to regard one's intentional experience as a whole as essentially detachable from the world at which it is directed. Seemingly crucial to their doubts about Husserl's reduction is their belief that an essential part of intentionality consists in a distinctively practical involvement with the world that cannot be broken by any mere abstention from judgment.

The phenomenological themes just hinted at (the notion of a 'pre-predicative' type of intentionality; the (un)detachability of intentionality from the world) link up with issues regarding consciousness and intentionality as these are understood outside the phenomenological tradition -- in particular, the notion of non-conceptual content, and the internalism/externalism debate, to be considered in Section (4). But it is

by no means a straightforward matter to describe these links in detail. Part of the reason lies in the general difficulty in being clear about whether what one philosopher means by ‘consciousness’ (or its standard translations) is close enough to what another means for it to be correct to see them as speaking to the same issues. And while some of the phenomenological philosophers (Brentano, Husserl, Sartre) make thematically central use of terms cognate with ‘consciousness’ and ‘intentionality,’ and consider questions about intentionality first and foremost as questions about the intentionality of consciousness, they do not explicitly address much that (in the latter half of the twentieth century) came to seem problematic about consciousness and intentionality. Is *their* ‘consciousness’ the *phenomenal* kind? Would they reject theories of consciousness that reduce it to a species of access to content? If so, on what grounds? (Note: given their interest in the relation of consciousness, inner perception, and reflection, it may be easier to discern what their stance on reductive ‘higher order representation’ theories of consciousness would be.)

In some ways the situation is more difficult still in the cases of Merleau-Ponty and Heidegger. For the former, though he willingly enough uses words standardly translated as ‘consciousness’ and ‘intentionality,’ says little to explain how he understands such terms generally. And the latter deliberately avoids these terms in his central work, *Being and Time*, in order to forge a philosophical vocabulary free of errors in which they had, he thought, become enmeshed. However, it is not obvious how to articulate the precise difference between what Heidegger rejects, in rejecting the allegedly error-laden understanding of ‘consciousness’ and ‘intentionality’ (or their German translations), and what he accepts when he speaks of beings ‘showing’ or ‘disclosing’ themselves to us, and of our ‘comportment’ directed towards them.

Nevertheless, one can plausibly read Brentano's notion of ‘presentation’ as equivalent to the notion of phenomenally conscious experience, as this is understood in other writers. For Brentano ([1874] 1973) says, ‘We speak of presentation whenever something appears to us.’ And one may take *ways of appearing* as equivalent to *ways of seeming*, in the sense proper to phenomenal consciousness. Further, Brentano's attempt to state in a ‘descriptive’ or ‘phenomenological’ psychology, based on how intentional presentations present themselves, the fundamental kinds to which they belong and their necessary interrelationships, may plausibly be interpreted as an effort to articulate the philosophically salient, highly general phenomenal character of intentional states (or acts) of mind. And Husserl's attempts to delineate the structure of intentionality as it is ‘given’ in consciousness, as well as the phenomenological productions of Sartre, can arguably be seen as devoted to laying bare to thought the deepest and most general characteristics of phenomenal consciousness, as they are found in ‘directed’ perception, judgment, imagination, emotion and action. Also, one might reasonably regard Heideggerean disclosure of the ready-to-hand and Merleau-Ponty's ‘motor-intentional’ consciousness of place as forms of phenomenally conscious experience -- as long as one's conception of phenomenal consciousness is not tied to the notion that the subjective ‘sphere’ of consciousness is, in essence, independent of the world revealed through it.

In any event, to connect classic phenomenological writings with current discussions of consciousness and its relation to intentionality, more background is needed on aspects of the other main current of Western philosophy in the past century particularly relevant to the topic of intentionality -- broadly labeled ‘analytic.’

4. Frege, Russell, and the Analytic Tradition

It seems fair to say that recent work in philosophy of mind in the analytic tradition that has focussed on questions about the nature of intentionality (or ‘mental content’) has been most formed not by the writings of Brentano, Husserl and their direct intellectual descendants, but by the seminal discussions of logico-linguistic concerns found in Gottlob Frege's (1892) “On Sense and Reference,” and Bertrand Russell's “On Denoting” (1905). (Roderick Chisholm (1957), much influenced by his study of Brentano, is a notable exception.)

But Frege's and Russell's work comes from much the same era, and from much the same intellectual environment as Brentano's and the early Husserl's. And fairly clear points of contact have long been recognized, such as: Russell's criticism of Meinong's ‘theory of objects’; and the similarities between Husserl's meaning/object distinction (in *Logical Investigation* I) and Frege's (prior) sense/reference distinction. Indeed the case has been influentially made (by Follesdal 1969, 1990) that Husserl's ‘meaning/object’ distinction is borrowed from Frege (though with a change in terminology) and that Husserl's ‘noema’ is properly interpreted as having the characteristics of Fregean ‘sense.’

Nonetheless, a number of factors make comparison and integration of debates within the two traditions complicated and strenuous. Husserl's notion of noema (hence his notion of intentionality) is most fundamentally rooted, not in reflections on the logical features of language, but in a contrast between the object of an intentional act, and the object ‘as intended’ (the way in which it is intended), and in the idea that a structure would remain to perceptual experience, even if it were radically non-veridical. And what Husserl seeks is a ‘direct’ characterization of this (and other) kinds of experience from the point of view of the experiencer. On the other hand, Frege's and Russell's writings bearing on the topic of intentionality concentrate mainly and most explicitly on issues that grow from their own pioneering achievements in logic, and have given rise to ways of understanding mental states primarily through questions about the logic and semantics of the language used to speak of them.

Broadly speaking, logico-linguistic concerns have been methodologically and thematically dominant in the analytic Frege-Russell tradition, while the phenomenological Brentano-Husserl lineage is rooted in attempts to characterize experience as it is evident from the subject's point of view. For this reason perhaps, discussions of consciousness and intentionality are more obviously intertwined from the start in the phenomenological tradition than in the analytic one. The following sketch of relevant background in the latter case will, accordingly, most directly concern the treatment of intentionality. But by the end, the bearing of this on the treatment of consciousness in analytic philosophy of mind will have become more evident, and it will be clearer how similar issues concerning the consciousness-intentionality relationship arise in each tradition.

Central to Frege's legacy for discussions of mental or intentional content has been his distinction between ‘sense’ (*Sinn*) and ‘reference’ (*Bedeutung*), and his use of this distinction to cope with the apparent failures of substitutivity of (ordinarily) co-referential expressions in contexts created by psychological

verbs, of the sort mentioned above in exposition of the notion of mental content -- a task important to his development of logic. The need for a distinction between the sense and reference of an expression became evident to Frege, when he considered that, even if *a* is identical to *b*, and you understand both ‘*a*’ and ‘*b*,’ still, it can be for you a *discovery*, an addition to your knowledge, that *a* = *b*. This is intelligible, Frege thought, only if you have different *ways* of understanding the expressions ‘*a*’ and ‘*b*’ -- only if they involve for you distinct ‘modes of presentation’ of the self-same object to which they refer. In Frege's celebrated example: you may understand the expressions ‘The Morning Star’ and ‘The Evening Star’ and use them to refer to what is one and the same object -- the planet Venus. But this is not sufficient for you to know that the Morning Star is identical with the Evening Star. For the ways in which an object (‘the reference’) is ‘given’ to your mind when you employ these expressions (the senses or *Sinne* you ‘grasp’ when you use them) may differ in such a manner that ignorance of astronomy would prevent your realizing that they are but two ways in which the same object can be given.

The relevance of all this to intentionality becomes clearer, once we see how Frege applied the sense/reference distinction to whole sentences. The sentence, ‘The Evening Star = The Morning Star’ has a different sense than the sentence ‘The Evening Star = The Evening Star’, even if their reference (according to Frege, their truth value) is the same. The failure of substitutivity of co-referential expressions in ‘that *p*’ contexts created by psychological verbs can consequently be understood (Frege proposed) in this way: the reference of the terms *shifts* in these contexts, so that, for example, ‘the Evening Star’ no longer refers to its customary reference (the planet Venus), but to a sense that functions, for the subject of the verb (the person who thinks, judges, desires) as his or her mode of presentation of this object. The sentence occurring in this context no longer refers to its truth value, but to the sense in which the mode of presentation is embedded -- which might otherwise be called the ‘thought’ -- or, by other philosophers, the ‘content’ of the subject's state of mind. This thought or content is to be understood not as a mental image, or indeed as anything essentially private to the thinker's mind -- but as one and the same abstract entity that can be ‘grasped’ by two minds, and that must be so grasped if communication is to occur.

While on the surface this story may appear to be only about logic and semantics, and though Frege did not himself elaborate a general account of intentionality, what he says readily suggests the following picture. Intentional states of mind -- thinking about Venus, wishing to visit it -- involve some special relation (such as ‘mental grasping’) -- not to a Venus ‘in one's mind,’ nor to an image of Venus, but -- to an abstract entity, a thought, which also constitutes the sense of a linguistic expression that can be used to report one's state of mind, a sense which is grasped or understood by speakers who use it.

This style of account, together with the Fregean thesis that ‘sense determines reference,’ and the history of criticisms both have elicited, form much of the background of contemporary discussions of mental content. It is often assumed, with Frege, that we must recognize (as some thinkers in the empiricist tradition allegedly did not) that thoughts or contents cannot consist in images or essentially private ‘ideas.’ But philosophers have frequently criticized Frege's view of thought as some abstract entity ‘grasped’ or ‘present to’ the mind, and have wanted to replace Frege's unanalyzed ‘grasping’ with something more ‘naturalistic.’

Relatedly, it may be granted that the content of the thought reported is to be identified with the sense of the expression with which we report it. But then, it is argued, the identity of this content will not be determined individualistically, and may in some respects lie beyond the grasp (or not be fully ‘present to’ the mind of) the psychological subject. For what determines the reference of an expression may be a natural causal relation to the world -- as Saul Kripke (1972) and Hilary Putnam (1975) have influentially argued is true for proper names, like ‘Nixon’ and ‘Cicero,’ and ‘natural kind’ terms like ‘gold’ and ‘water.’ Or (as Tyler Burge (1979) has influentially argued) two speakers who, considered as individuals, are qualitatively the same, may nevertheless each assert something different simply because of differing relations they bear to their respective linguistic communities. (For example, what one speaker's utterance of ‘arthritis’ means is determined not by what is ‘in the head’ of that speaker, but by the medical experts in his or her community.) And, if reference and truth conditions of expressions by which one's thought is reported or expressed are not determined by what is in one's head, and the content of one's thought determines their reference and truth conditions, then the content of one's thought is also not determined individualistically. Rather it is necessarily bound up with one's causal relations to certain natural substances, and one's membership in a certain linguistic community. Both linguistic meaning and mental contents are ‘externally’ determined.

The development of such ‘externalist’ conceptions of intentionality informs the reception of Russell's legacy in contemporary philosophy of mind as well. Russell also helped to put in play a conception of the intentionality of mental states, according to which each such state is seen as involving the individual's ‘acquaintance with a proposition’ (counterpart to Fregean ‘grasping’) -- which proposition is at once both what is understood in understanding expressions by which the state of mind is reported, and the content of the individual's state of mind. Thus, intentional states are ‘propositional attitudes.’ Also importantly, Russell's famous analysis of definite descriptions into phrases employing existential quantifiers and general predicates underlay many subsequent philosophers' rejection of any conception of intentionality (like Meinong's) that sees in it a relation to non-existent objects. And, Russell's treatment drew attention to cases of what he called ‘logically proper names’ that apparently defy such analysis in descriptive terms (paradigmatically, the terms ‘this’ and ‘that’), and which (he thought) thus must refer ‘directly’ to objects. Reflection on such ‘demonstrative’ and ‘indexical’ (e.g., ‘I,’ ‘here,’ ‘now’) reference has led some (Kaplan 1979, Perry 1977) to maintain that the content of our states of mind cannot always be constituted by Fregean senses but must be seen as consisting partly of the very objects in the world outside our heads to which we refer, demonstratively, indexically -- another source of support for an ‘externalist’ view of mental content, hence, of intentionality.

Yet another important source of externalist proclivities in twentieth century philosophy lies in the thought that the meaningfulness of a speaker's utterances depends on its potential intelligibility to hearers: *language must be public* -- an idea that has found varying and influential expression in the work of Ludwig Wittgenstein, W.V.O. Quine, and Donald Davidson. This, coupled with the assumption that intentionality (or ‘thought’ in the broad (Cartesian) sense) must be expressible in language, has led some to conclude that what determines the content of one's mind must lie in the external conditions that enable others to attribute content.

However, the movement from Frege and Russell toward externalist views of intentionality should not

simply be accepted as yielding a fund of established results: it has been subject to powerful and detailed challenges (by Searle (1983), and Kirk Ludwig (1996b), for example). But without plunging into the details of the internalism/externalism debate about mental content, we can recognize, in the issues just raised, certain themes bearing particularly on the connection between consciousness and intentionality.

For example: it is sometimes assumed that, whatever may be true of content or intentionality, the phenomenal character of one's experience, at least, is ‘fixed internally’ -- i.e., it involves no necessary relations to the nature of particular substances in one's external environment or to one's linguistic community. But then the purported externalist finding that neither meaning nor content is ‘in the head’ may be read as showing the insufficiency of phenomenal consciousness to determine any intentionality or content. Something like this consequence is drawn by Putnam (1981), who takes the stream of consciousness to comprise nothing more than sensations and images, which (as Frege saw) should be sharply distinguished from thought and meaning. This interpretation of the import of externalist arguments may be reinforced by a tendency to tie (phenomenal) consciousness to non-intentional sensations, sensory qualities, or ‘raw feels,’ and hence to dissociate consciousness from intentionality (and allied notions of meaning and reference), a tendency that has been prominent in the analytic tradition (perhaps largely through the influence of that Ryle (1949) and Wittgenstein (1953) -- (see Section (7)).

But it is not at all evident that externalist theories of content require us to estrange consciousness from intentionality. One might argue (as do Martin Davies (1997) and Fred Dretske (1997)) that in certain relevant respects the phenomenal character of experience is also essentially determined by causal environmental connections. By contrast, one may argue (as do Ludwig (1996b) and Horgan and Tienson (2002)) that since it is conceivable that a subject have experience much like our own in phenomenal character, but radically different in external causes from what we take our own to be (in the extreme case, a mind bewitched by a Cartesian demon into massive hallucination), there must indeed be a realm of mental content that is *not* externally determined.

One other aspect of the Frege-Russell tradition of theorizing about content that impinges on the consciousness/intentionality connection is this. If ‘content’ is identified with the sense or the truth-condition determiners of the expressions used in the object-clause reporting intentional states of mind, it will seem natural to suppose that possession of mental content requires the possession of conceptual capacities of the sort involved in linguistic understanding -- ‘grasping senses.’ But then, to the extent the phenomenal character of experience is inadequate to endow a creature with such capacities, it may seem that phenomenal consciousness has little to do with intentionality.

But this raises large issues. One is this: it should not be granted without question that the phenomenal character of our experience could be as it is in the absence of the sorts of conceptual capacities sufficient for (at least some types of) intentionality. And this is tied to the issue of whether or not the phenomenal character of experience is (as some suppose) a purely sensory affair. Some would maintain, on the contrary, that thought (not just imagistic, but conceptual thought) has phenomenal character too. (See Flanagan 1992, Horgan and Tienson 2002, Siewert 1998, Strawson 1994.) If so, then it is very far from clear that phenomenal character can be divorced from whatever conceptual capacities are necessary for intentionality.

Moreover we may ask: are *concepts*, properly speaking, always necessary for intentionality anyway? Here another issue rears its head: is there not perhaps a form of *sensory* intentionality, which does not require anything as distinctively intellectual or conceptual as is needed for the grasping of linguistic senses or propositions? (This presumably would be a kind of intentionality had by the pre-linguistic (e.g., babies) or by non-linguistic creatures (e.g., dogs).) Suppose that there is, and that this type of intentionality is inseparable from the phenomenal character of perceptual experience. Then, even if one assumes that such phenomenal consciousness is insufficient to guarantee the possession of concepts, it would be wrong to say that it has little to do with intentionality. (Advocates of varying versions of the idea that there is a distinctively ‘non-conceptual’ kind of content include Bermudez 1998, Crane 1992, Evans 1982, Peacocke 1992, and Tye 1995 -- for a notable voice of opposition to this trend, see McDowell 1994.) A deep difficulty in assessing these debates lies in getting an acceptable conception of *concepts* to work with. We need to understand clearly what ‘having a concept of *F*’ does and does not require, before we can be clear about the content of and justification for the thesis of *non*-conceptual content.

These proposals about non-conceptual content bear some affinity with aspects of the phenomenological tradition alluded to earlier: Husserl's notion of ‘pre-predicative’ experience; Heidegger's treatment of the ‘ready-to-hand;’ and Merleau-Ponty's idea that in normal active perception we are conscious of place, not via a determinate ‘representation’ of it, but rather, relative to our capacities for goal-directed bodily behavior. Though to see the extent to which any of these are ‘non-conceptual’ in character would require not only more clarity about the conceptual/non-conceptual contrast, but considerable novel exegesis of these philosophers' works. (For one recent effort to draw a connection between phenomenological and analytic traditions on the issue of ‘non-conceptual content’ see Kelly 2001.)

Also, one may plausibly try to find an affinity between externalist views in analytic philosophy, and the later phenomenologists' rejection of Husserl's reduction, based on their doubt that we can prise consciousness off from the world at which it is directed, and study its ‘intentional essence’ in solipsistic isolation. But if externalism can be defined broadly enough to encompass Heidegger, Merleau-Ponty, Kripke, and Burge, still the comparison is strained when we take account of the different sources of ‘externalism’ in the phenomenologists. These have to do it seems (very roughly) with the idea that the way we are conscious of things (or at least, for Heidegger, the way they ‘show themselves’ to us) in our everyday activity cannot be quite generally separated from our actual engagement with entities of which we are thus conscious (which show themselves in this way). Also relevant is the idea that one's use of language (hence one's capacity for thought) requires gearing one's activity to a social world or cultural tradition, in which antecedently employed linguistic meaning is taken up and made one's own through one's relation with others. All this is supposed to make it infeasible to study the nature of intentionality by globally uprooting, in thought, the connection of experience with one's spatial surroundings (and -- crucially for Merleau-Ponty -- one's own body), and one's social environment. Whatever the merits of this line of thought, we should note: neither a causal connection with ‘natural kinds’ unmediated by reference-determining ‘modes of presentation,’ nor deference to the linguistic usage of specialists, nor belief in the need to reconstruct speaker's meaning from observed behavior, plays a role in the phenomenologists' doubts about the reduction.

The arduous exegesis required for a clearer and more detailed comparison of these views is not possible here. Nevertheless, following some of the main lines of thought in treatments of intentionality, descending on the one hand, primarily from Brentano and Husserl, and on the other, from Frege and Russell, certain fundamental issues concerning its relationship to consciousness have emerged. These include, first, the connection between consciousness and self-directed or self-reflexive intentionality. (It has already been seen that this topic preoccupied Brentano, Husserl and Sartre; its emergence as an important issue in analytic philosophy of mind will become more evident below, in Section 6.) Second, there is concern with the way in which (and the extent to which) mind is world-involving. (In the phenomenological tradition this can be seen in controversy over Husserl's phenomenological reduction; within the analytic tradition, in the critique of Fregean sense and the internalism/externalism debate.) Third, there is the putative distinction between conceptual or theoretical, and sensory or practical forms of intentionality. (In phenomenology this shows up in Husserl's contrast between judgment and pre-predicative experience, and related notions of his successors; in analytic philosophy this shows up in the (more recent) attention to the notion of ‘non-conceptual’ content.)

For more clarity regarding the consciousness-intentionality relationship and how these three topics figure prominently in views about it, it is necessary now to turn attention back to philosophical disagreements regarding consciousness that are much bound up with the distinctions mentioned in Section (1), among phenomenal consciousness, access consciousness, and reflexive consciousness.

5. Consciousness and Sensory Content

Consider the proposal that sense experience manifests a kind of intentionality distinct from and more basic than that involved in propositional thought and conceptual understanding. This might help form the basis for an account of consciousness. Perhaps conscious states of mind are distinguished partly by their possession of a type of content proper to the sensory subdivision of mind.

One source of the idea that a difference in type of content helps constitute a distinction between what is and is not phenomenally conscious, lies in the apparent distinction between sense experience and judgment. To have conscious *visual experience* of a stimulus -- for it to look some way to you -- is one thing. To make judgments about it is something else. (This seems evident in the persistence of a visual illusion, even once one has become convinced of the error.) However, on some accounts of consciousness, this distinction itself is doubtful, since conscious sense experience is taken to be nothing more than a form a judging. Such a view is expressed by Daniel Dennett (1991), who takes the relevant form of judging to consist in one's possession of information or mental content available to the appropriate sort of ‘probes’ -- the availability of content he calls ‘cerebral celebrity.’ For Dennett what distinguishes conscious states of mind is not their possession of a distinctive type of intentional content, but rather the richness of that content, plus its availability to the appropriate sort of cognitive operations. (Since the relevant class of operations is not sharply defined, neither, for Dennett, is the difference between which states of mind are conscious and which are not.)

Recent accounts of consciousness that, by contrast, give central place to a distinction between

(conceptual) judgment and (non-conceptual -- but still intentional) sense-experience include Michael Tye's (1995) theory, holding that it is (by metaphysical necessity) sufficient to have a conscious sense-perception that some representation of sensory stimuli is formed in one's head, ‘map-like’ in character, whose (‘non-conceptual’) content is ‘poised’ to affect one's (conceptual) beliefs. This form of mental representation Tye would contrast with the ‘sentential’ form proper to belief and judgment -- and in that way, he might preserve the judgment/experience contrast as Dennett does not. Consider also Fred Dretske's (1995) view, that phenomenally conscious sensory intentionality consists in a kind of mental representation whose content is bestowed through a naturally selected ‘function to indicate.’ Such natural (evolution-implanted) sensory representation can arise independently of learning (unlike the more conceptual, language dependent sort), and is found widely distributed among evolved life.

Both Tye's and Dretske's views of consciousness (unlike Dennett's) make crucial use of a contrast between the types of intentionality proper to sense-experience, and that proper to linguistically expressed judgment. On the other hand, there is also some similarity among the theories, which can be brought out by noting a criticism of Dennett's view, analogues of which arise for Tye's and Dretske's views as well.

Some might think Dennett's account concerns only some variety of what Block would call ‘access consciousness.’ For on Dennett's account, it seems, to speak of visual consciousness is to speak of nothing over and above the sort of availability of informational content that is evinced in unprompted verbal discriminations of visual stimuli. And this view has been criticized for neglecting phenomenal consciousness. (See Block 1995 and Siewert 1998.) It seems we may conceive of a capacity for spontaneous judgment triggered by and responsive to visual stimuli, which would occur in the absence of the judger's phenomenally conscious visual experience of the stimuli: the stimuli don't *look* any way to the subject, and yet they trigger accurate judgments about their presence. The notion of such a (hypothetical) form of ‘blindsight’ may be elaborated in such a way that we conceive of the judgment it affords as being at least as finely discriminatory (and as fine in informational content) as that enjoyed by those with extremely poor, blurry and un-acute conscious visual experience (as in the ‘legally blind’).But a view like Dennett's seems to make this scenario inconceivable.

However, this kind of criticism does not concern only those theories that would elide any experience/judgment distinction. For Tye's and Dretske's theories, though they depend on forms of that contrast (and are offered as theories of *phenomenal* consciousness), can raise similar concerns. For one might think that the hypothetical blindsighter would be as rightly regarded as having Tye's ‘poised’ maplike representations in her visual system as would someone with a comparable form of conscious vision. And one might find it unclear why we should think the visual system of such a blindsighter must be performing naturally endowed indicating functions more poorly than the visual system of a consciously sighted subject would.

Whatever the cogency of these concerns, one should note their distinctness from the issues about ‘kinds of intentionality’ that appear to separate both Tye and Dretske from Dennett. The notion that there is a fundamental distinction to be drawn in kinds of intentional content (separating the more intellectual from the more sensory departments of mind) sometimes forms the basis of an account of consciousness (as with Dretske's and Tye's, though not with Dennett's). But it is also important to recognize what unites

Dennett, Tye, and Dretske. Despite their differences, all propose to account for consciousness by starting with a general understanding of intentionality (or mental content or representation) to which consciousness is inessential. They then offer to explain consciousness as a special case of intentionality thus understood -- so, in terms of the operations the content is available for, or the form in which it is represented, or the nature of its external source. The blindsight-based objection to Dennett, and its possible extension to Dretske and Tye, helps bring this commonality to light.

6. Consciousness and Higher Order Representation

The last section showed how some theories purport to account for consciousness on the basis of intentionality, in a way that focuses attention on attempts to discern a distinctively sensory type of intentionality. A different strategy for explaining consciousness via intentionality highlights the importance of clarity regarding the connection between consciousness and reflexivity. On such a view (roughly): experiences or states of mind are conscious just insofar as the mind represents itself as having them.

In David Rosenthal's (1986, 1991, 1993) variant of this approach, a state is conscious just when it is a kind of (potentially non-conscious) mental state one has, which one (seemingly without inference) thinks that one is in. A theory of this sort starts with some way of classifying mental states that is supposed to apply to conscious and non-conscious states of mind alike. The proposal then is that such a state is conscious just when it belongs to one of those mental kinds, and the ('higher order') thought occurs to the person in that state that he or she is in a state of that kind. So, for example it is maintained that certain non-conscious states of mind can possess 'sensory qualities' of various sorts -- one may, in a sense, be *in* pain without feeling pain, one may have a red sensory quality, even when nothing looks red to one. The idea is that one has a conscious visual experience of red, or a conscious pain sensation, just when one has such a red sensory quality, or pain-quality, and the thought (itself also potentially non-conscious) occurs to one that one has a red sensory quality, or pain-quality.

This way of accounting for consciousness in terms of intentionality may, like theories mentioned in Section 5, provoke the concern that the distinctively phenomenal sense of consciousness has been slighted -- though this time, not in favor of some 'access' consciousness, but in favor of reflexive consciousness. One focus of such criticism lies in the idea that such higher-order thought requires the possession of concepts -- concepts of types of mental states -- that may be lacking in creatures with first order mentality. And it is unclear (in fact it seems false to say) these beings would therefore have no conscious sensory experience in the phenomenal sense. Mightn't there be a way the world looks to rabbits, dogs, monkeys, and human babies, and mightn't they feel pain, though they lack the conceptual wherewithal to think about their own experience?

One line of response to such concerns is simply to bite the bullet: dogs, babies and the like might altogether lack higher order thought, but that's no problem for the theory because, indeed, they also altogether lack *feelings* (Carruthers 1989). Rosenthal, for his part, takes a different line: lack of cognitive sophistication needn't instantly disqualify one for consciousness, since the possession of primitive

mentalistic concepts requires so little that practically any organism we would consider a serious candidate for sensory consciousness (certainly babies, dogs and bunnies) would obviously pass muster.

A number of additional worries have been raised about both the necessity and the sufficiency of ‘higher order thought’ for conscious sense experience. (See, for example, Dretske 1993, Guzeldere 1997, Seager 1999, and Siewert 1998.) In the face of such doubts, one may preserve the idea that consciousness consists in some kind of higher order representation -- the mind's ‘scanning’ itself -- by abandoning ‘higher order thought’ for some other form of representation: one which is not thought-like or conceptual, but somehow *sensory* in character (Lycan 1996). Maybe somewhat as we can distinguish between primitive sensory perception of things in our environment, and the more intellectual, conceptual operations based on them, so we can distinguish the thoughts we have about our own (‘inner’) mental goings-on from the (‘inner’) sensing of them. And, if we propose that consciousness consists in this latter sort of higher order representation, it seems we will escape the worries occasioned by the Rosenthalian variant of the ‘reflexivist’ doctrine. In considering such theories, two of the consciousness-themes earlier discerned come together, namely: reflexivity (or higher order representation), and the contrast between the conceptual and non-conceptual (or sensory).

Criticism of ‘inner sense’ theories is likely to focus not so much on the thought that such inner sensing can occur without phenomenal consciousness, or that the latter can occur without the former, as on the difficulty in understanding just what inner sensing (as distinct from higher order thought) is supposed to be, and why we should think we have it. It seems the inner sense theorists share with those who distinguish between conceptual and non-conceptual (or sensory) flavors of intentionality the challenge of clarifying and justifying some version of this distinction. But they bear the additional burden of showing how such a distinction can be applied not just to intentionality directed at tables and chairs, but at the "furniture of the mind" as well. One may grant that there are non-conceptual sensory experiences of objects in one's external environment while doubting one has anything analogous regarding the ‘inner’ landscape of mind.

It should be noted that, in spite of the difficulties faced by higher order representation theories, they draw on certain perennially influential sources of philosophical appeal. We do have some willingness to speak of conscious states of mind as states we are conscious or aware *of* being in. It is tempting to interpret this as indicating some kind of reflexivity. And the history of philosophy reveals many thinkers attracted to the idea that consciousness is inseparable from some kind of self-reflexivity of mind. As noted varying versions of this idea can be found in Brentano, Husserl, and Sartre. And we can go further back: Kant (1787) spoke explicitly of ‘inner sense,’ and Locke (1690) defined consciousness as the ‘perception of what passes in a man's mind.’ Brentano (controversially) interpreted Aristotle's enigmatic and terse discussion of “seeing that one sees” in *De Anima* III.2 as an anticipation of his own ‘inner perception’ view.

However, there is this critical difference between the thinkers just cited and contemporary purveyors of higher order representation theories. The former do not maintain, as do the latter, that consciousness consists in one's forming the right sort of higher order representation of a possibly non-conscious type of mental state. Even if they think that consciousness is inseparable from some sort of mental reflexivity,

they do not suggest that consciousness can, so to speak, be analyzed into mental parts, none of which themselves essentially require consciousness. (Some could not maintain this, since they explicitly deny mentality without consciousness.) There is a difference between saying that reflexivity is essential to consciousness and saying that consciousness just consists in or is reducible to a species of mental reflexivity. Advocacy of the former without advocacy of the latter is certainly possible. (See, for example, Smith 1986, Levine 2001, Ludwig 2001.)

7. Is Phenomenal Consciousness Intentional?

Suppose one holds that phenomenal consciousness is distinguishable both from ‘access’ and ‘reflexivity,’ and that it cannot be explained as a special case of intentionality. One might conclude from this that phenomenal consciousness and intentionality comprise two quite distinct realms of the mental, and embrace the idea that the phenomenal is a matter of non-intentional qualia or raw feels. One important current in the analytic tradition has evinced this attitude -- it is found, for example, in Wilfrid Sellars' (1956) distinction between ‘sentience’ (sensation) and ‘sapience.’ Whereas the qualities of *feelings* involved in the former -- mere sensations -- require no cognitive sophistication and are readily attributable to brutes, the latter -- involving awareness *of*, awareness *that* -- requires that one have the appropriate concepts, which cannot be guaranteed by just having sensations; one needs learning and inferential capacities of a sort Sellars believed possible only with language. “Awareness,” Sellars says, “is a linguistic affair.”

Thus we may arrive at a picture of mind that places sensation on one side, and thought, concepts, and ‘propositional attitudes’ on the other. If one recognizes a distinctively phenomenal consciousness not captured in ‘representationalist’ theories of the kinds just scouted, one may then want to say: that is because the phenomenal belongs to mere sentience, and the intentional to sapience. Other influential philosophers of mind have operated with a similar picture. Consider Gilbert Ryle's (1949) contention that the stream of consciousness contains nothing but sensations that provide “no possibility of deciding whether the creature that had these was an animal or a human being; an idiot, a lunatic, or a sane man” -- nothing of which it is appropriate to ask whether it is correct or incorrect, veridical or nonveridical. And Wittgenstein's (1953) influential criticisms of the notion of understanding as an ‘inner process,’ and of the idea of a language for private sensation divorced from public criteria, could be interpreted in ways that sever (phenomenal) consciousness from intentionality. (Such an interpretation would assume that if consciousness could secure understanding, understanding *would* be an ‘inner process,’ and if phenomenal character bore intentionality with it, private sensations *could* impart meaning to words.) Also recall Putnam's conviction that the (internal) stream of consciousness cannot furnish the (externally fixed) content of meaning and belief. A similar attitude is evident in Donald Davidson's (1983, 1986) distinction between sensation and thought (the former is nothing more than a causal condition of knowledge, while the latter can furnish reasons and justifications, but cannot occur without language). Richard Rorty (1979) makes a Sellarsian distinction between the phenomenal and the intentional key to his polemic against epistemological philosophy in general, and ‘foundationalism’ in particular (and takes a generally deflationary view of the phenomenal or ‘qualitative’ side of this divide).

But it is possible to reject attempts to subsume the phenomenal under the intentional as in the 'representationalist' accounts of consciousness variously exemplified in Dennett, Dretske, Lycan, Rosenthal,and Tye, without adopting this 'two separate realms' conception. We can believe that there is no conception of the intentional from which the phenomenal can be explanatorily derived that does not already include the phenomenal, but still believe also that the phenomenal character of experience cannot be separated from its intentionality, and that having experience of the right sort of phenomenal character is sufficient for having certain forms of intentionality (McGinn 1991, Horgan and Tienson 2002, Siewert 1998). Here one might leave open the question whether there is also some kind of phenomenal character (perhaps that involved in some kinds of bodily sensation or after-images) whose possession is *not* sufficient for intentionality. (Though if we say there is such non-intentional phenomenal character, this would give us a special reason for rejecting the representationalist explanations of phenomenal consciousness mentioned in Section 5.) If, on the other hand, we say phenomenal character always brings intentionality with it, that might be 'representationalism' of a sort. But its endorsement is consistent with a rejection of attempts to derive phenomenality from intentionality, or reduce the former to a species of the latter, which commonly attract the 'representationalist' label. We should distinguish the question of whether the phenomenal can be *explained by* the intentional from the question of whether the phenomenal is *separable from* the intentional.

Closer consideration of two of the three themes earlier identified as common to phenomenological and analytic traditions is needed to come to grips with the latter question. It is necessary to inquire: (a) whether an externalist conception of intentionality can justify separating phenomenal character from intentionality. And one needs to ask: (b) whether one's verdict on the 'separability' question stands or falls with acceptance of some version of a distinction between conceptual and non-conceptual (or distinctively sensory) forms of intentionality.

The dialectical situation regarding (a) is complex. One way it may seem plausible to answer question (a) in the affirmative, and restrict phenomenal character and intentionality to different sides of some internal/external divide, is to conduct a Cartesian thought experiment, in which one conceives of consciousness with all its subjective riches surviving the utter annihilation of the spatial realm of nature. (Similarly, but less radically, one may conceive of a 'brain in a vat' generating an extended history of sense experience indistinguishable in phenomenal character from that of an embodied subject.) If one is committed to an externalist view of intentionality -- but rejects the intentionalizing strategies of Sections (5) and (6) for dealing with consciousness -- one may conclude that phenomenal character is altogether separable from (and insufficient for) intentionality. However, one may draw rather different conclusions from the Cartesian thought experiment -- turning it *against externalism*. It may seem to one that, since the intentionality of experience would apparently survive along with its phenomenal character, one may then infer that the causal tie between the mind's content and the world of objects beyond it that (according to some versions of externalism) fixes content, is in reality and in at least some cases (or for some contents), no more than contingent. (This is the lesson Husserl, Ludwig, Horgan and Tienson would draw.)

Alternatively, whatever one relies on to argue that this or that relation of experience and world is essential to having any intentionality at all, one may well take this to show that phenomenal character is also externally determined in a way that renders the Cartesian scenario of consciousness totally unmoored

from the world an illusion. And, if Merleau-Ponty or Heidegger think that Husserl's phenomenological reduction to a sphere of ‘pure’ consciousness cannot be completed, and their reasons make them externalists of some sort, it hardly seems to establish that they are committed to a (Sellarsian or Rylean) realm of raw sensory phenomenal consciousness, devoid of intentionality. In fact their rejection of Husserl's notion of ‘uninterpreted’ sensory or ‘hyletic’ data in experience would seem to indicate they, at least, would strongly deny they held such views.

In this arena it is far from clear what we are entitled to regard as secure ground and what as ‘up for grabs.’ However, there do seem to be ways in which all would probably admit that the phenomenal character of experience and externally individuated content come apart, ways in which such content goes beyond anything phenomenal consciousness can supply. For the way it seems to me to experience this computer screen may be no different from the way it seems to my twin to experience some entirely distinct one. Thus where intentional contents are distinguished in such a way as to include the particular objects experienced or thought of, phenomenal character cannot determine the possession of content. Still, that does not show that no content of any sort is fixed by phenomenal character. Perhaps, as some would say, phenomenal character determines ‘narrow’ or ‘notional’ content, but not ‘wide’ (externally ‘fixed’) content. Nor is it even clear that we must judge the sufficiency of phenomenal character for intentionality by adopting some general account of content and its individuation (as ‘narrow’ or ‘wide’ for instance), and then ask whether one's possession of content so considered is entailed by the phenomenal character of one's experience. One may argue that the phenomenal character of one's experience suffices for intentionality as long as having it makes one assessable for truth, accuracy (or other sorts of ‘satisfaction’) without the addition of any interpretation, properly so-called, such as is involved in assessment of the truth or accuracy of sentences or pictures (Siewert 1998).

Even if one does not globally divide phenomenal character from intentionality along some inner/outer boundary line, to address questions of the sufficiency of phenomenal character for intentionality (and thus of the separability of the latter from the former), one still needs to look at question (b) above, and the potential relevance of distinctions that have been proposed between conceptual and non-conceptual forms of content or intentionality. Again the situation is complex. Suppose one regards the notion of non-conceptual intentionality or content as unacceptable on the grounds that all content is conceptual. But suppose one also thinks it is clear that phenomenal character is confined to sensory experience and imagery, and that this cannot bring with it the rational and inferential capacities required for genuine concept possession. Then one will have accepted the separability of phenomenal consciousness from intentionality. However, one may, by contrast, take the apparent susceptiblity of phenomenally conscious sense experience to assessment for accuracy, without need for additional, potentially absent interpretation, to show that the phenomenal character of experience is inherently intentional. Then one will say that the burden lies on anyone who claims conceptual powers are crucial to such assessability and can be detached from the possession of such experience: they must identify those powers and show that they are both crucial and detachable in this way. Additionally (as noted in Section 4), one may reasonably challenge the assumption that phenomenal consciousness is indeed confined to the sensory realm; one may say that conceptual thought also has phenomenal character. Even if one does not, one may still base one's confidence in the sufficiency of phenomenal character for intentionality on one's confidence that there is a kind of non-conceptual intentionality that clearly belongs essentially to sense experience. (Such

presumably would be Michael Tye's position.)

these considerations, we can see that it is critical to answer the following questions in order to decide whether or not phenomenal character is wholly or significantly separable from intentionality.

i. Does every sort of intentionality that belongs to thought and experience require external connections for which phenomenal character is insufficient?
ii. Does every sort of intentionality that belongs to sense-experience and sensory imagery require conceptual abilities for which phenomenal character is insufficient?
iii. Does every sort of intentionality that belongs to thought require conceptual capacities for which phenomenal character is insufficient?

Suppose one finds phenomenal character quite generally inadequate for the intentionality of thought and sense-experience by answering ‘yes’ either to (i), or to both (ii) and (iii). And suppose one makes the plausible (if non-trivial) assumption that what guarantees intentionality for neither sensory experience, nor imagery, nor conceptual thought, guarantees no intentionality that belongs to our minds (including that of emotion, desire and intention -- for these latter presuppose the former). Then one will find phenomenal character altogether separable from intentionality. Phenomenal character could be as it is, even if intentionality were completely taken away. There is no form of phenomenal consciousness, and no sort of intentionality, such that the first suffices for the second.

A more moderate view might merely answer only one of either (ii) or (iii) in the affirmative (and probably (iii) would be the choice). But still, in that case one recognizes some broad mental domain whose intentionality is in no repsect guaranteed by phenomenal character. And that too would mark a considerable limitation on the extent to which phenomenal consciousness brings intentionality with it.

On the other hand, suppose that one answers ‘no’ to (i), and to either (ii) or (iii). Now, external connections and conceptual capacities seem to be what we might most plausibly regard as conditions necessary for the intentionality of thought and experience that could be stripped away while phenomenal character remains constant. So if one thinks that actually neither are generally essential to intentionality and removable while phenomenal character persists unchanged, and one can think of nothing else that is essential for thought and experience to have any intentionality, but for which phenomenal character is insufficient, it seems reasonable to conclude that phenomenal character is indeed sufficient for intentionality of some sort. If one has gone this far, it seems unlikely that one will then think that actual differences in phenomenal character still leave massively underdetermined the different forms of intentionality we enjoy in perceiving and thinking. So, one will probably judge that some kind of phenomenal character suffices for, and is inseparable from, many significant forms of intentionality in at least one of these domains (sensory or cognitive): there are many differences in phenomenal character, and many in intentionality, such that you cannot have the former without the latter. If one also rejects both (ii) and (iii), then one will accept that (appropriate forms of) phenomenal consciousness are sufficient for a very broad and important range of human intentionality.

8. Is Phenomenality Essential to Intentionality?

Suppose one rejects both the view that consciousness is explanatorily derived from a more fundamental intentionality, as well as the view that phenomenal character is insufficient for intentionality because it is a matter of pure inward feel. It seems one might then press farther, and argue for what Flanagan (1992) calls ‘consciousness essentialism’ -- the view that the phenomenal character of experience is not only sufficient for various forms of intentionality, but necessary also.

This type of thesis needs careful formulation. It does not necessarily commit one to a Cartesian (or Brentanian or Sartrean) claim that all states of mind are conscious -- a total denial of the reality of the unconscious. A more qualified thesis does seem desirable. Freud's waning prestige has weakened tendencies to assume that he had somehow demonstrated the reality of unconscious intentionality, the rise of cognitive science has created a new climate of educated opinion that also takes elaborate non-conscious mental machinations for granted. Even if we do not acquiesce in this view, we do (and long have) appealed to explanations of human behavior that recognize some sort of intentional states other than phenomenally conscious experiences and thoughts.

One way of maintaining the necessity of consciousness to mind that can preserve some space for mind that is not conscious is Searle's (1990, 1992). He argues, roughly, that we should first distinguish between what he calls ‘intrinsic’ intentionality on the one hand, and merely ‘as if’ intentionality, and ‘interpreter relative’ intentionality, on the other. We sometimes may speak *as if* artifacts (like thermostats) had beliefs or desires -- but this isn't to be taken literally. And we may impose ‘conditions of satisfaction’ on our acts and creations (words, pictures, diagrams, etc.) by our *interpretation* of them -- but they have no intentionality independent of our interpretive practices. Intrinsic intentionality, on the other hand -- the kind that pertains to our beliefs, perception, and intentions -- is neither a mere ‘manner of speech,’ nor is our possession of it derived from others' interpretive stance towards us. But then, Searle asks, what accounts for the fact that some states of affairs in world have intrinsic intentionality -- that they are directed at objects under aspects -- and why they are directed under the aspects they are (why they have the content they do)? With conscious states of mind, Searle says, their phenomenal or subjective character determines their ‘aspectual shape.’ Where non-conscious states of mind are concerned, there is nothing to do the job, but their relationship to consciousness. The right relationship, he holds, is this: non-conscious states of mind must be ‘potentially conscious.’ If some psychological theories (of language, of vision) postulate an unconscious so deeply buried that its mental representations cannot even potentially become conscious, so much the worse for those theories.

Searle's views have aroused a number of criticisms. (See the peer commentary in response to Searle 1990.) Among the problem areas are these. First, how are we to spell out the requirement that intrinsically intentional states be ‘potentially conscious,’ without making it either too easy or to difficult to satisfy? Second, just why is it that the intrinsic intentionality of non-conscious states needs accounting for, while that of conscious states is somehow unproblematic? Third, it appears Searle's argument does not offer some general reason to rule out all efforts to give ‘naturalistic’ accounts of conditions sufficient to impose -- without the help of consciousness -- genuine and not merely interpreter relative intentionality.

Another approach is taken by Kirk Ludwig (1996a), who argues that there is nothing to determine *whose* state of mind a given non-conscious state of mind is, unless that state consists in a disposition to produce a conscious mental state of the right sort. Alleged mental processes that did not tend to produce someone's conscious states of mind appropriately would be no one's, which is to say that they would not be mental states at all. Roughly: consciousness is needed to provide that unity of mind without which there would be no mind. And Ludwig argues that it is therefore a mistake to attribute many of the unconscious inferences with which psychological theorists have long been wont to populate our minds.

The persuasiveness of Searle's and Ludwig's arguments depends heavily on demonstrating the failure of alternative accounts of the job that they enlist consciousness to do (such as secure ‘aspectual shape,’ or ownership). One may well grant (as does Colin McGinn 1991) that phenomenal character is inseparable from intentionality, but cannot be explained by it, while still maintaining that genuine intentionality (mental content) is quite adequately imposed on animal brains by their acquisition of natural functions of content-bearing -- in which consciousness evidently plays no essential role. Or one may (like Jerry Fodor 1987) maintain a robustly realist ‘representational theory of mind,’ proposing that the content of mental symbols is stamped on them by their being in the ‘right causal relation’ to the world -- while despairing of the prospects for a credible naturalistic theory of consciousness.

9. Four Views of the Consciousness-Intentionality Relationship

The preceding discussion has conveyed some of the complexities and potential ambiguities in talk of ‘consciousness’ (Section 1) and ‘intentionality’ (Section 2) that must be appreciated if one is to resolve questions about the relationship between consciousness and intentionality with any clarity. Brief surveys of relevant aspects of phenomenological (Section 3) and analytic (Section 4) traditions have brought out some shared areas of interest, namely: the relationship of consciousness to reflexivity and ‘self-directed’ intentionality; efforts to distinguish between conceptual and non-conceptual (or sensory) forms of intentionality; and a concern with the extent to which the character of either conscious experience or intentional states of mind is essentially ‘world-involving.’ These concerns were seen to bear on attempts to account for consciousness in terms of intentionality in Sections 5 and 6, and also on questions that arise even if those attempts are rejected -- questions regarding the separability of phenomenal consciousness and intentionality (Section 7). In Section 8 some attention was given to views that, in some sense, reverse the order of explanation proposed by intentionalizing views of consciousness, and take the facts of consciousness to explain the facts of intentionality. Now it is possible to step back and distinguish four general views of the consciousness-intentionality relationship discernable in the philosophical positions canvassed above, as follows.

a. Consciousness is explanatorily derived from intentionality.
b. Consciousness is underived and separable from intentionality.
c. Consciousness is underived but also inseparable from intentionality.
d. Consciousness is underived from, inseparable from, and essential to intentionality.

To adopt view (a) is to accept some intentionalizing strategy with respect to consciousness, such as is variously represented by Dennett, Dretske, Lycan, Rosenthal, and Tye. These views differ importantly among themselves, and their differences have much to do with how they treat consciousness-reflexivity issues and the conceptual/non-conceptual (or conceptual/sensory) contrast, and how they view the intersection between the two. But if we adopt (a), then our answer to the question of what consciousness has to do with intentionality will ultimately be given in some prior general account of content or intentionality. And there will be no special issue regarding the internal or external fixation of the phenomenal character of experience, over and above what arises for mental content generally.

On the other hand, suppose one rejects (a), and holds that experiences are conscious in a phenomenal sense that does not yield to an approach in which one conceives of intentionality (or content, or information bearing) independently of consciousness, and then, by adverting to special operations, or sources, or contents, tells us what consciousness is. At this point, one would face a choice between (b) and (c).

Adopting (b) yields the ‘raw feel’ conception of phenomenality seemingly implicit in Sellars and Ryle. If, on the other hand, we adopt (c), we endorse a much more intimate relationship between consciousness and intentionality. Without proposing to account for the former on the basis of the latter, we would hold that phenomenal character is sufficient for intentionality.

But adoption of (c) leaves open a further basic question. Consciousness (of the appropriate sort) may be sufficient for (but underived from) intentionality, and yet, intentionality does not require consciousness. Thus we come to ask whether having conscious experience of an appropriate sort is necessary to having either sensory or more-than-sensory (conceptual) intentionality.

If adopting thesis (d), we say ‘yes’ -- that such intentionality can come only with consciousness -- we will probably have gone as far in making consciousness fundamental to mind as one reasonably can. Again, this is not necessarily to deny the reality of non-conscious mental phenomena. But it could, in a broad way, be interpreted as siding with Husserl, Ludwig and Searle in thinking of consciousness as the irreplaceable source of intentionality and meaning.

This abstract list of four options might leave one without a sense of what is at stake in adopting this or that view. Perhaps the positions themselves will become a little clearer if we make explicit four broad areas of philosophical concern to which the choice among them is relevant.

First, they are relevant to the issue of how to conceive of the mind or the domain of psychology *as a whole*. Is there some *unity* to the concept of mind or psychological phenomenal? Is there something that deserves to be considered the essence of the mental? If consciousness can be thoroughly intentionalized (as (a) would have it), maybe (with suitable qualifications), we could uphold the thesis that intentionality is the "mark of the mental." If we reject (a) and embrace (c), seeing intentionality as inseparable from the phenomenal character of experience, then we still might maintain that both consciousness and intentionality are necessary for real minds -- at least, if we adopt (d) as well. But a unified view of the

mind seems difficult (if not impossible) to maintain if one segregates phenomenal character to non-intentional sensation -- as in (b). Even if one does not, one may lack a unifying conception of the mental domain, if one is not satisfied with arguments that show that phenomenal consciousness is essential to genuine (not merely “as if” or “interpreter derived”) intentionality. In any case, both consciousness and intentionality are broad enough psychological categories, that one's view of their extension and relationship will do much to draw one's map of psychology's terrain.

Second (and relatedly), views about the consciousness-intentionality relationship bear significantly on general questions about the *explanation* of mental phenomena. One may ask what kinds of things we might try to explain in the mental domain, what sorts of explanations we should seek, and what prospects of success we have in finding them. If we accept (a) and some intentionalizing account of consciousness, we will not suppose as do some (Chalmers 1996, Levine 2001, McGinn 1991, and Nagel 1974) that phenomenal consciousness poses some specially recalcitrant (maybe hopelessly unsolvable) problem for reductive physicalist or materialist explanations. Rather, we will see the basic challenge as that of giving a natural scientific account of intentionality or mental representation. And this indeed is a reason some are attracted to (a). One may believe that it offers us the only hope for a natural scientific understanding of consciousness. The underlying thought is that a science of consciousness must adopt this strategy: first conceive of intentionality (or content or mental representation) in a way that separates it from consciousness, and see intentionality as the outcome of familiar (and non-intentional) natural causal processes. Then, by further specifying the kind of intentionality involved (in terms of its use, its sources, its content), we can account for consciousness. In other words: ‘naturalize’ intentionality, then intentionalize consciousness, and mind has found its place in nature.

However, we should recognize a distinction between those whose envisioned naturalistic explanation would require underlying forms of necessity and impossibility stronger that that pertaining to laws of nature generally -- such as either conceptual or ‘metaphysical’ necessity -- and those who see the link between explanans and explanandum as simply one of natural scientific law. David Chalmers' (1996) proposals for ‘naturalistic dualism’ (unlike those of the aforementioned naturalizers) put him in the second group. He argues that phenomenal consciousness in its various forms supervenes (not conceptually or metaphysically but only as a matter of nature's laws) on functional organization, and that this permits us to envisage (‘non-reductive’) ways of explaining consciousness by appeal to such organization.

Those who reject attempts to explain the phenomenal consciousness via a theory of intentionality still may reasonably proclaim allegiance to ‘naturalism.’ One may take phenomenal consciousness to be, in a sense, *psychologically* basic (if all that is mental is either phenomenally conscious or intentional, and no intentionalizing account of phenomenal character is feasible). But one might still hold that some non-intentional neuropsychological (or other, recognizably physicalist) explanation of the phenomenal character of experience is to be had, either because the explanatory link here exhibits an appropriately strong (conceptual or metaphysical) necessity, or because nothing stronger than psychophysical laws of nature are needed to give us the prospect of a natural scientific account of consciousness.

However, if we not only reject intentionalizing accounts of phenomenal character, but also see it as

inseparable from intentionality (if we reject both (a) and (b) and accept (c)), then whatever problems attach to physicalist explanations of consciousness will also infect prospects for explaining intentionality -- to some extent at least. And this will hold, even if we remain aloof from (d), and do not claim that phenomenal consciousness is essential to intentionality. For if we think that much of the intentionality we have in perceiving, imagining, and thinking is integral to the phenomenal character of such experience, then without a reductive explanation of that phenomenal character, our possession of the intentionality it brings with it will not be reductively explained either.

Finally, it should be noted that if one holds (d), this may have important consequences for what forms of psychological explanation one finds acceptable. For Searle and Ludwig argue that one's mental processes must have the right relationship to one's conscious experiences to count as one's mental processes at all. If they are right, postulated processes that do *not* bear this relation to our experiential lives cannot be going on in our minds.

A third broad area of concern on which our choice among (a)-(d) bears is epistemological. If one adopts (b), and something like a Sellarsian or Davidsonian distinction between sensation and thought, putting phenomenal character exclusively on the ‘sensation’ side, and intentionality exclusively on the ‘thought’ side of this divide, the place of consciousness in a philosophical account of knowledge will likely be meager -- at most phenomenal character will be a causal condition, without a role to play in the warrant or justification of claims to knowledge. However, if one takes route (a) or (c) the situation will appear rather different. If one either intentionalizes consciousness, or else views intentionality as inseparable from phenomenal character, there will then be more room to view consciousness as central to accounts of the warrant involved in first-person (‘introspective’) knowledge of mind, and empirical or perceptual knowledge. Though just how one goes about this, and with what success, will depend on how (if one chooses (a)) one intentionalizes consciousness, and (if one chooses (a) or (c)), that will depend on what sort of intentionality or content one thinks phenomenal consciousness brings with it. The place of consciousness in one's understanding of introspective or empirical knowledge will be rather different, depending on how one resolves the issues regarding: reflexivity; the conceptual/non-conceptual distinction; and externalism.

A fourth area of philosophical concern we may indicate broadly, closely bound to our conception of the relation of consciousness and intentionality, has to do with *value*. How intimately is consciousness bound up with those features of our own and others' lives that give them intrinsic or non-instrumental value for us? We may think that the pleasure and suffering that demand our ethical concern are necessarily phenomenally conscious -- and that this evaluative significance remains even if phenomenal character is non-intentional. However, the more intentionality is seen as inherent to the phenomenal character of experience, the more the latter will be bound to manifestations of intelligence, emotion, and understanding that appear to give human (and perhaps at least some other animal life) its special importance for us.

It may seem that those opting for (c) share at least this much ground with their intentionalizing opponents who go for (a): they both (unlike those who adopt (b)) are in a position to claim consciousness is crucial to whatever special moral regard we think appropriate only towards those whose psychologies involve a

kind of intentionality for which possession of painful or pleasant experience is not sufficient. However, this needs qualification on two counts. First, if one's embrace of (a) includes an intentionalizing strategy that limits phenomenal character to the sensory realm, one will limit the moral significance of phenomenal consciousness accordingly. Second, to those who hold (c), it may well seem their opponents' intentionalizing theories remove from view those very qualities of experience that make life worth living, and so they will hardly seem like allies on the issue of value. Further, if the proponent of (c) balks at going so far as to take on (d) -- conscious essentialism -- those who make that additional commitment may well wonder how those who do not could ultimately accord the possession of consciousness much greater non-instrumental value than the possession of a sophisticated but totally non-conscious mind.

From this survey it seems fair to conclude that working out a detailed view of the relation between consciousness and intentionality is hardly a peripheral matter philosophically. Potentially it has far-reaching consequences for one's views concerning these four important, broad topics:

- *The unity of mental phenomena* (Do consciousness or intentionality (or both together) somehow unify the domain of the psychological?)
- *The explanation of mental phenomena* (Can consciousness and intentionality be explained separately? Is explaining the one key to explaining the other?)
- *Introspective and empirical knowledge* (What relation to intentionality would give consciousness a central epistemological role in either?)
- *The value of human and other animal life*. (What relation of consciousness and intentionality (if any) underlies the non-instrumental value we accord ourselves and others?)

Higher-order Theories of Consciousness

Higher-order theories of consciousness try to explain the distinctive properties of consciousness in terms of some relation obtaining between the conscious state in question and a higher-order representation of some sort (either a higher-order experience of that state, or a higher-order thought or belief about it). The most challenging properties to explain are those involved in *phenomenal* consciousness -- the sort of state which has a *subjective* dimension, which has 'feel', or which it is *like something* to undergo. These properties will form the focus of this article.

---

1. Kinds of Consciousness

One of the advances made in recent years has been in distinguishing between different questions concerning consciousness (see particularly: Rosenthal, 1986; Dretske, 1993; Block, 1995; Lycan, 1996). Not everyone agrees on quite *which* distinctions need to be drawn. But all are agreed that we should distinguish *creature* consciousness from *mental-state* consciousness. It is one thing to say *of an individual person or organism* that it is conscious (either in general or of something in particular); and it is quite another thing to say *of one of the mental states* of a creature that it is conscious.

It is also agreed that within creature-consciousness itself we should distinguish between *intransitive* and *transitive* variants. To say of an organism that it is conscious *simpliciter* (intransitive) is to say just that it is awake, as opposed to asleep or comatose. There do not appear to be any deep philosophical difficulties lurking here (or at least, they are not difficulties specific to the topic of consciousness, as opposed to

mentality in general). But to say of an organism that it is conscious *of such-and-such* (transitive) is normally to say at least that it is *perceiving* such-and-such, or *aware of* such-and-such. So we say of the mouse that it is conscious of the cat outside its hole, in explaining why it does not come out; meaning that it *perceives* the cat's presence. To provide an account of transitive creature-consciousness would thus be to attempt a theory of perception.

There is a choice to be made concerning transitive creature-consciousness, failure to notice which may be a potential source of confusion. For we have to decide whether the perceptual state in virtue of which an organism may be said to be transitively-conscious of something must itself be a conscious one (state-conscious -- see below). If we say 'Yes' then we shall need to know more about the mouse than merely that it perceives the cat if we are to be assured that it is conscious of the cat -- we shall need to establish that its percept of the cat is itself conscious. If we say 'No', on the other hand, then the mouse's perception of the cat will be sufficient for the mouse to count as conscious of the cat; but we may have to say that although it is conscious of the cat, the mental state in virtue of which it is so conscious is not itself a conscious one! It may be best to by-pass any danger of confusion here by avoiding the language of transitive-creature-consciousness altogether. Nothing of importance would be lost to us by doing this. We can say simply that organism O *observes* or *perceives* X; and we can then assert explicitly, if we wish, that its percept is or is not conscious.

Turning now to the notion of *mental-state consciousness*, the major distinction here is between *phenomenal consciousness*, on the one hand -- which is a property of states which it is *like something* to be in, which have a distinctive 'feel' (Nagel, 1974) -- and various functionally-definable forms of *access consciousness*, on the other (Block, 1995). Most theorists believe that there are mental states -- such as occurrent thoughts or judgments -- which are access-conscious (in whatever is the correct functionally-definable sense), but which are not phenomenally conscious. In contrast, there is considerable dispute as to whether mental states can be phenomenally-conscious without also being conscious in the functionally-definable sense -- and even more dispute about whether phenomenal consciousness can be *reductively explained* in functional and/or representational terms.

It seems plain that there is nothing deeply problematic about functionally-definable notions of mental-state consciousness, from a naturalistic perspective. For mental functions and mental representations are the staple fare of naturalistic accounts of the mind. But this leaves plenty of room for dispute about the form that the correct functional account should take. Some claim that for a state to be conscious in the relevant sense is for it to be poised to have an impact on the organism's decision-making processes (Kirk, 1994; Dretske, 1995; Tye, 1995), perhaps also with the additional requirement that those processes should be distinctively *rational* ones (Block, 1995). Others think that the relevant requirement for access-consciousness is that the state should be suitably related to higher-order representations -- experiences and/or beliefs -- of that very state (Armstrong, 1968, 1984; Rosenthal, 1986, 1993; Dennett, 1991; Carruthers, 1996, 2000; Lycan, 1996).

What *is* often thought to be naturalistically problematic, in contrast, is phenomenal consciousness (Nagel, 1974, 1984; Jackson, 1982, 1986; McGinn, 1991; Block, 1995; Chalmers, 1996). And what is really and deeply controversial is whether phenomenal consciousness can be *explained* in terms of some or other

functionally-definable notion. *Cognitive* (or *representational*) theories maintain that it can. *Higher-order* cognitive theories maintain that phenomenal consciousness can be reductively explained in terms of representations (either experiences or beliefs) which are higher-order. It is such theories which concern us here.

2. The Motivation for a Higher-Order Approach

Higher-order theories, like cognitive / representational theories in general, assume that the right *level* at which to seek an explanation of phenomenal consciousness is a cognitive one, providing an explanation in terms of some combination of *causal role* and *intentional content*. All such theories claim that phenomenal consciousness consists in a certain kind of intentional or representational content (*analog* or 'fine-grained' in comparison with any concepts we may possess) figuring in a certain distinctive position in the causal architecture of the mind. They must therefore maintain that these latter sorts of mental property do not already implicate or presuppose phenomenal consciousness. In fact, all cognitive accounts are united in rejecting the thesis that the very properties of *mind* or *mentality* already presuppose phenomenal consciousness, as proposed by Searle (1992, 1997) for example.

The major divide amongst representational theories of phenomenal consciousness in general, is between accounts which are provided in purely first-order terms and those which implicate higher-order representations of one sort or another (see below). These higher-order theorists will allow that first-order accounts -- of the sort defended by Dretske (1995) and Tye (1995), for example -- can already make some progress with the problem of consciousness. According to first-order views, phenomenal consciousness consists in analog or fine-grained contents which are available to the first-order processes which guide thought and action. So a phenomenally-conscious percept of red, for example, consists in a state with the analog content *red* which is tokened in such a way as to feed into thoughts about red, or into actions which are in one way or another guided by redness. Now, the point to note in favor of such an account is that it can explain the natural temptation to think that phenomenal consciousness is in some sense *ineffable*, or *indescribable*. This will be because such states have fine-grained contents which can slip through the mesh of any conceptual net. We can always distinguish many more shades of red than we have concepts for, or could describe in language (other than indexically -- e.g., '*That* shade').

The main motivation behind higher-order theories of consciousness, in contrast, derives from the belief that all (or at least most) mental-state types admit of both conscious and non-conscious varieties. Almost everyone now accepts, for example, (post-Freud) that beliefs and desires can be activated non-consciously. (Think, here, of the way in which problems can apparently become resolved during sleep, or while one's attention is directed to other tasks. Notice, too, that appeals to non-conscious intentional states are now routine in cognitive science.) And then if we ask what makes the difference between a conscious and a non-conscious mental state, one natural answer is that conscious states are states we are *aware of*. And if *awareness* is thought to be a form of creature-consciousness (see section 1 above), then this will translate into the view that conscious states are *states of which the subject is aware*, or states of which the subject is creature-conscious. That is to say, these are states which are the objects of some sort of higher-order representation -- whether a higher-order perception or experience, or a higher-order belief or

thought.

One crucial question, then, is whether perceptual states as well as beliefs admit of both conscious and non-conscious varieties. Can there be, for example, such a thing as a non-conscious visual perceptual state? Higher-order theorists are united in thinking that there can. Armstrong (1968) uses the example of absent-minded driving to make the point. Most of us at some time have had the rather unnerving experience of ‘coming to’ after having been driving on ‘automatic pilot’ while our attention was directed elsewhere -- perhaps having been day-dreaming or engaged in intense conversation with a passenger. We were apparently not consciously aware of any of the route we have recently taken, nor of any of the obstacles we avoided on the way. Yet we must surely have been *seeing*, or we would have crashed the car. Others have used the example of blindsight (Carruthers, 1989, 1996). This is a condition in which subjects have had a portion of their primary visual cortex destroyed, and apparently become blind in a region of their visual field as a result. But it has now been known for some time that if subjects are asked to *guess* at the properties of their ‘blind’ field (e.g. whether it contains a horizontal or vertical grating, or whether it contains an ‘X’ or an ‘O’), they prove remarkably accurate. Subjects can also reach out and grasp objects in their ‘blind’ field with something like 80% or more of normal accuracy, and can catch a ball thrown from their ‘blind’ side, all without conscious awareness. (See Weiskrantz, 1986, 1997, for details and discussion.)

More recently, a powerful case for the existence of non-conscious visual experience has been generated by the *two-systems theory* of vision proposed and defended by Milner and Goodale (1995). They review a wide variety of kinds of neurological and neuro-psychological evidence for the substantial independence of two distinct visual systems, instantiated in the temporal and parietal lobes respectively. They conclude that the parietal lobes provide a set of specialized semi-independent modules for the on-line visual control of action; whereas the temporal lobes are primarily concerned with more off-line functions such as visual learning and object recognition. And only the experiences generated by the temporal-lobe system are phenomenally conscious, on their account.

(Note that this is not the familiar distinction between *what* and *where* visual systems, but is rather a successor to it. For the temporal-lobe system is supposed to have access both to property information and to spatial information. Instead, it is a distinction between a combined *what-where* system located in the temporal lobes and a *how-to* or action-guiding system located in the parietal lobes.)

To get the flavor of Milner and Goodale's hypothesis, consider just one strand from the wealth of evidence they provide. This is a neurological syndrome called *visual form agnosia*, which results from damage localized to both temporal lobes, leaving primary visual cortex and the parietal lobes intact. (Visual form agnosia is normally caused by carbon monoxide poisoning, for reasons which are little understood.) Such patients cannot recognize objects or shapes, and may be capable of little conscious visual experience; but their sensorimotor abilities remain largely intact.

One particular patient -- D.F. -- has now been examined in considerable detail. While D.F. is severely agnosic, she is not completely lacking in conscious visual experience. Her capacities to perceive colors and textures are almost completely preserved. (Why just these sub-modules in her temporal cortex should

have been spared is not known.) As a result, she can sometimes guess the identity of a presented object -- recognizing a banana, say, from its yellow color and the distinctive texture of its surface. But she is unable to perceive the shape of the banana (whether straight or curved, say); nor its orientation (upright or horizontal; pointing towards her or across). Yet many of her sensorimotor abilities are close to normal -- she would be able to reach out and grasp the banana, orienting her hand and wrist appropriately for its position and orientation, and using a normal and appropriate finger grip. Under experimental conditions it turns out that although D.F. is at chance in identifying the orientation of a broad line or letter-box, she is almost normal when posting a letter through a similarly-shaped slot oriented at random angles. In the same way, although she is at chance when trying to discriminate between rectangular blocks of very different sizes, her reaching and grasping behaviors when asked to pick up such a block are virtually indistinguishable from those of normal controls. It is very hard to make sense of this data without supposing that the sensorimotor perceptual system is functionally and anatomically distinct from the object-recognition/conscious system.

There is a powerful case, then, for thinking that there are non-conscious as well as conscious visual percepts. While the perceptions which ground your thoughts when you plan in relation to the perceived environment (‘I'll pick up *that* one’) may be conscious, and while you will continue to enjoy conscious perceptions of what you are doing while you act, the perceptual states which actually guide the details of your movements when you reach out and grab the object will *not* be conscious ones, if Milner and Goodale (1995) are correct.

But what implications does this have for phenomenal consciousness? Must these non-conscious percepts also be lacking in *phenomenal* properties? Most people think so. While it may be possible to get oneself to believe that the perceptions of the absent-minded car driver can remain phenomenally conscious (perhaps lying outside of the focus of attention, or being instantly forgotten), it is very hard to believe that either blindsight percepts or D.F.'s sensorimotor perceptual states might be phenomenally conscious ones. For these perceptions are ones to which the subjects of those states are *blind*, and of which they cannot be a*ware*. And the question, then, is what makes the relevant difference? What is it about a conscious perception which renders it *phenomenal*, which a blindsight perceptual state would correspondingly lack? Higher-order theorists are united in thinking that the relevant difference consists in the presence of something *higher-order* in the first case which is absent in the second. The core intuition is that a phenomenally conscious state will be a state *of which the subject is aware*.

What options does a first-order theorist have to resist this conclusion? One is to deny the data (as does Dretske, 1995). It can be said that the non-conscious states in question lack the kind of fineness of grain and richness of content necessary to count as genuinely *perceptual* states. On this view, the contrast discussed above isn't really a difference between conscious and non-conscious perceptions, but rather between conscious perceptions, on the one hand, and non-conscious belief-like states, on the other. Another option is to accept the distinction between conscious and non-conscious perceptions, and then to explain that distinction in first-order terms. It might be said, for example, that conscious perceptions are those which are available to *belief* and *thought*, whereas non-conscious ones are those which are available to guide *movement* (Kirk, 1994). A final option is to bite the bullet, and insist that blindsight and sensorimotor perceptual states are indeed phenomenally conscious while not being *access*-conscious. (See

Block, 1995; Tye, 1995; and Nelkin, 1996; all of whom defend versions of this view.) On this account, blindsight percepts are phenomenally conscious states to which the subjects of those states are *blind*. Higher-order theorists will argue, of course, that none of these alternatives is acceptable (see, e.g., Carruthers, 2000).

In general, then, higher-order theories of phenomenal consciousness claim the following:

> **Higher Order Theory (In General)**:
> A phenomenally conscious mental state is a mental state (of a certain sort -- see below) which either is, or is disposed to be, the object of a higher-order representation of a certain sort (see below).

Higher-order theorists will allow, of course, that mental states can be targets of higher-order representation without being phenomenally conscious. For example, a belief can give rise to a higher-order belief without thereby being phenomenally conscious. What is distinctive of phenomenal consciousness is that the states in question should be perceptual or quasi-perceptual ones (e.g. visual images as well as visual percepts). Moreover, most cognitive/representational theorists will maintain that these states must possess a certain kind of analog (fine-grained) or non-conceptual intentional content. What makes perceptual states, mental images, bodily sensations, and emotional feelings phenomenally conscious, on this approach, is that they are conscious states with analog or non-conceptual contents. So putting these points together, we get the view that phenomenally conscious states are those states *which possess fine-grained intentional contents of which the subject is aware*, being the target or potential target of some sort of higher-order representation.

There are then two main dimensions along which higher-order theorists disagree amongst themselves. One concerns whether the higher-order states in question are belief-like or perception-like. Those taking the former option are higher-order *thought* theorists, and those taking the latter are higher-order *experience* or ‘inner-sense’ theorists. The other disagreement is internal to higher-order thought approaches, and concerns whether the relevant relation between the first-order state and the higher-order thought is one of *availability* or not. That is, the question is whether a state is conscious by virtue of being *disposed* to give rise to a higher-order thought, or rather by virtue of being the *actual target* of such a thought. These are the options which will now concern us.

3. Inner-Sense Theory

According to this view, humans not only have first-order non-conceptual and/or analog perceptions of states of their environments and bodies, they also have second-order non-conceptual and/or analog perceptions of their first-order states of perception. Humans (and perhaps other animals) not only have sense-organs which scan the environment/body to produce fine-grained representations which can then serve to ground thoughts and action-planning, but they also have *inner* senses, charged with scanning the outputs of the first-order senses (i.e. perceptual experiences) to produce equally fine-grained, but higher-order, representations of those outputs (i.e. to produce higher-order experiences). A version of this view

was first proposed by the British Empiricist philosopher John Locke (1690). In our own time it has been defended especially by Armstrong (1968, 1984) and by Lycan (1996).

(A terminological point: this view is sometimes called a ‘higher-order experience (HOE) theory’ of phenomenal consciousness; but the term ‘inner-sense theory’ is more accurate. For as we shall see in section 5, there are versions of a higher-order thought (HOT) approach which also implicate higher-order perceptions, but without needing to appeal to any organs of inner sense.)

(Another terminological point: ‘*inner*-sense theory’ should more strictly be called ‘*higher-order*-sense theory’, since we of course have senses which are physically ‘inner’, such as pain-perception and internal touch-perception, which are not intended to fall under its scope. For these are first-order senses on a par with vision and hearing, differing only in that their purpose is to detect properties of the body rather than of the external world. According to the sort of higher-order theory under discussion in this section, these senses, too, will need to have their outputs scanned to produce higher-order analog contents in order for them to become phenomenally conscious. In what follows, however, the term ‘inner sense’ will be used to mean, more strictly, ‘higher-order sense’, since this terminology is now pretty firmly established.)

We therefore have the following proposal to consider:

> **Inner-Sense Theory**:
> A phenomenally conscious mental state is a state with analog/non-conceptual intentional content, which is in turn the target of a higher-order analog/non-conceptual intentional state, via the operations of a faculty of ‘inner sense’.

On this account, the difference between a phenomenally conscious percept of red and the sort of non-conscious percepts of red which guide the guesses of a blindsighter and the activity of sensorimotor system, is as follows. The former is scanned by our inner senses to produce a higher-order analog state with the content *experience of red* or *seems red*, whereas the latter states are not -- they remain *merely* first-order states with the analog content *red*; and in so remaining, they lack any dimension of *seeming* or *subjectivity*. According to inner-sense theory, it is our higher-order experiential contents produced by the operations of our inner-senses which make some mental states with analog contents, but not others, available to their subjects. And it is these same higher-order contents which constitute the subjective dimension or ‘feel’ of the former set of states, thus rendering them phenomenally conscious.

One of the main advantages of inner-sense theory is that it can explain how it is possible for us to acquire *purely recognitional concepts* of experience. For if we possess higher-order perceptual contents, then it should be possible for us to learn to recognize the occurrence of our own perceptual states immediately -- or ‘straight off’ -- grounded in those higher-order analog contents. And this should be possible without those recognitional concepts thereby having any conceptual connections with our beliefs about the nature or content of the states recognized, nor with any of our surrounding mental concepts. This is then how inner-sense theory will claim to explain the familiar philosophical thought-experiments concerning one's own experiences, which are supposed to cause such problems for physicalist/naturalistic accounts of the mind (Kripke, 1972; Chalmers, 1996).

For example, I can think, '*This* type of experience [as of red] might have occurred in me, or might normally occur in others, in the absence of any of its actual causes and effects.' So on any view of intentional content which sees content as tied to normal causes (i.e. to information carried) and/or to normal effects (i.e. to teleological or inferential role), *this* type of experience might occur without representing *red*. In the same sort of way, I shall be able to think, '*This* type of experience [pain] might have occurred in me, or might occur in others, in the absence of any of the usual causes and effects of pains. There could be someone in whom *these* experiences occur but who isn't bothered by them, and where those experiences are never caused by tissue damage or other forms of bodily insult. And conversely, there could be someone who behaves and acts just as I do when in pain, and in response to the same physical causes, but who is never subject to *this* type of experience.' If we possess purely recognitional concepts of experience, grounded in higher-order percepts of those experiences, then the thinkability of such thoughts is both readily explicable, and apparently unthreatening to a naturalistic approach to the mind.

Inner-sense theory does face a number of difficulties, however. One objection is as follows (see Dretske, 1995). If inner-sense theory were true, then how is it that there is no phenomenology distinctive of inner sense, in the way that there is a phenomenology associated with each outer sense? Since each of the outer senses gives rise to a distinctive set of phenomenological properties, you might expect that if there *were* such a thing as inner sense, then there would also be a phenomenology distinctive of its operation. But there doesn't appear to be any.

This point turns on the so-called 'transparency' of our perceptual experience (Harman, 1990). Concentrate as hard as you like on your 'outer' (first-order) experiences -- you will not find any *further* phenomenological properties arising out of the attention you pay to them, beyond those already belonging to the contents of the experiences themselves. Paying close attention to your experience of the color of the red rose, for example, just produces attention to the *redness* -- a property of the rose. But put like this, however, the objection just seems to beg the question in favor of first-order theories of phenomenal consciousness. It assumes that first-order -- 'outer' -- perceptions already have a phenomenology independently of their targeting by inner sense. But this is just what an inner-sense theorist will deny. And then in order to explain the absence of any kind of higher-order phenomenology, an inner-sense theorist only needs to maintain that our higher-order experiences are never themselves targeted by an inner-sense-organ which might produce *third*-order analog representations of them in turn.

Another objection to inner-sense theory is as follows (see Sturgeon, 2000). If there really were an organ of inner sense, then it ought to be possible for it to malfunction, just as our first-order senses sometimes do. And in that case, it ought to be possible for someone to have a first-order percept with the analog content *red* causing a higher-order percept with the analog content *seems-orange*. Someone in this situation would be disposed to judge, 'It's red', immediately and non-inferentially (i.e. not influenced by beliefs about the object's normal color or their own physical state). But at the same time they would be disposed to judge, 'It *seems* orange'. Not only does this sort of thing never apparently occur, but the idea that it might do so conflicts with a powerful intuition. This is that our awareness of our own experiences is *immediate*, in such a way that to *believe* that you are undergoing an experience of a certain sort *is* to be

undergoing an experience of that sort. But if inner-sense theory is correct, then it ought to be possible for someone to believe that they are in a state of *seeming-orange* when they are actually in a state of *seeming-red*.

A different sort of objection to inner-sense theory is developed by Carruthers (2000). It starts from the fact that the internal monitors postulated by such theories would need to have considerable computational complexity in order to generate the requisite higher-order experiences. In order to perceive an experience, the organism would need to have mechanisms to generate a set of internal representations with an analog or non-conceptual content representing the content of that experience, in all its richness and fine-grained detail. And notice that any inner scanner would have to be a physical device (just as the visual system itself is) which depends upon the detection of those *physical* events in the brain which are the outputs of the various sensory systems (just as the visual system is a physical device which depends upon detection of physical properties of surfaces via the reflection of light). For it is hard to see how any inner scanner could detect the presence of an experience *qua* experience. Rather, it would have to detect the physical *realizations* of experiences in the brain, and construct the requisite higher-order representation of the experiences which those physical events realize, on the basis of that physical-information input. This makes is seem inevitable that the scanning device which supposedly generates higher-order experiences of our first-order visual experience would have to be almost as sophisticated and complex as the visual system itself.

Now the problem which arises here is this. Given this complexity in the operations of our organs of inner sense, there had better be some plausible story to tell about the evolutionary pressures which led to their construction. For natural selection is the only theory which can explain the existence of organized functional complexity in nature (Pinker, 1994, 1997). But there would seem to be no such stories on the market. The most plausible suggestion is that inner-sense might have evolved to subserve our capacity to think about the mental states of conspecifics, thus enabling us to predict their actions and manipulate their responses. (This is the so-called 'Machiavellian hypothesis' to explain the evolution of intelligence in the great-ape lineage. See Byrne and Whiten, 1988, 1998.) But this suggestion presupposes that the organism must *already* have some capacity for higher-order *thought*, since it is such thoughts which inner sense is supposed to subserve. And yet as we shall see shortly (in section 5), some higher-order thought theories can claim all of the advantages of inner-sense theory as an explanation of phenomenal consciousness, but without the need to postulate any 'inner scanners'. At any rate, the 'computational complexity objection' to inner-sense theories remains as a challenge to be answered.

4. Higher-Order Thought Theory (1): Non-dispositionalist

Non-dispositionalist higher-order thought (HOT) theory is a proposal about the nature of state-consciousness in general, of which phenomenal consciousness is but one species. Its main proponent has been Rosenthal (1986, 1993, forthcoming). The proposal is this: a conscious mental state M, of mine, is a state which is actually causing an activated belief (generally a non-conscious one) that I have M, and

causing it non-inferentially. (The qualification concerning non-inferential causation is included to avoid one having to say that my non-conscious motives become conscious when I learn of them under psycho-analysis, or that my jealousy is conscious when I learn of it by interpreting my own behavior.) An account of phenomenal consciousness can then be generated by stipulating that the mental state M should have an analog content in order to count as an experience, and that when M is an experience (or a mental image, bodily sensation, or emotional feeling), it will be phenomenally conscious when (and only when) suitably targeted.

We therefore have the following proposal to consider:

> **Non-Dispositionalist Higher-Order Thought Theory**:
> A phenomenally conscious mental state is a state with analog/non-conceptual intentional content, which is the object of a higher-order thought, and which causes that thought non-inferentially.

This account avoids some of the difficulties inherent in inner-sense theory, while retaining the latter's ability to explain the distinction between conscious and non-conscious perceptions. (Conscious perceptions will be analog states which are targeted by a higher-order thought, whereas perceptions such as those involved in blindsight will be non-conscious by virtue of *not* being so targeted.) In particular, it is easy to see a function for higher-order thoughts, in general, and to tell a story about their likely evolution. A capacity to entertain higher-order thoughts about experiences would enable a creature to negotiate the is/seems distinction, perhaps learning not to trust its own experiences in certain circumstances, and also to induce appearances in others, by deceit. And a capacity to entertain higher-order thoughts about thoughts (beliefs and desires) would enable a creature to reflect on, and to alter, its own beliefs and patterns of reasoning, as well as to predict and manipulate the thoughts and behaviors of others. Indeed, it can plausibly be claimed that it is our capacity to target higher-order thoughts on our own mental states which underlies our status as rational agents (Burge, 1996; Sperber, 1996).

One well-known objection to this sort of higher-order thought theory is due to Dretske (1993). We are asked to imagine a case in which we carefully examine two line-drawings, say (or in Dretske's example, two patterns of differently-sized spots). These drawings are similar in almost all respects, but differ in just one aspect -- in Dretske's example, one of the pictures contains a black spot which the other lacks. It is surely plausible that, in the course of examining these two pictures, one will have enjoyed a conscious visual experience of the respect in which they differ -- e.g. of the offending spot. But, as is familiar, one can be in this position while not knowing *that* the two pictures are different, or in what *way* they are different. In which case, since one can have a conscious experience (e.g. of the spot) without being aware that one is having it, consciousness cannot require higher-order awareness.

Replies to this objection have been made by Seager (1994) and by Byrne (1997). They point out that it is one thing to have a conscious experience of the aspect which differentiates the two pictures, and quite another to consciously experience that the two pictures are differentiated by that aspect. That is, seeing the extra spot in one picture needn't mean seeing that this is the difference between the two pictures. So while scanning the two pictures one will enjoy conscious experience of the extra spot. A higher-order

thought theorist will say that this means undergoing a percept with the content *spot here* which forms the target of a higher-order belief that one is undergoing a perception with that content. But this can perfectly well be true without one undergoing a percept with the content *spot here in this picture but absent here in that one*. And it can also be true without one forming any higher-order belief to the effect that one is undergoing a perception with the content *spot here* when looking at a given picture but not when looking at the other. In which case the purported counter-example isn't really a counter-example.

A different sort of problem with the non-dispositionalist version of higher-order thought theory relates to the huge number of beliefs which would have to be caused by any given phenomenally conscious experience. (This is the analogue of the ‘computational complexity’ objection to inner-sense theory, sketched in section 3 above). Consider just how rich and detailed a conscious experience can be. It would seem that there can be an immense amount of which we can be consciously aware at any one time. Imagine looking down on a city from a window high up in a tower-block, for example. In such a case you can have phenomenally conscious percepts of a complex distribution of trees, roads, and buildings; colors on the ground and in the sky above; moving cars and pedestrians; and so on. And you can -- it seems -- be conscious of all of this simultaneously. According to non-dispositionalist higher-order thought theory, then, you would need to have a distinct activated higher-order belief for each distinct aspect of your experience -- either that, or just a few such beliefs with immensely complex contents. Either way, the objection is the same. For it seems implausible that all of this higher-order activity should be taking place (albeit non-consciously) every time someone is the subject of a complex conscious experience. For what would be the point? And think of the amount of cognitive space that these beliefs would take up!

This objection to non-dispositionalist forms of higher-order thought theory is considered at some length in Carruthers (2000), where a variety of possible replies are discussed and evaluated. Perhaps the most plausible and challenging such reply would be to deny the main premise lying behind the objection, concerning the rich and integrated nature of phenomenally conscious experience. Rather, the theory could align itself with Dennett's (1991) conception of consciousness as highly fragmented, with multiple streams of perceptual content being processed in parallel in different regions of the brain, and with no stage at which all of these contents are routinely integrated into a phenomenally conscious perceptual manifold. Rather, contents become conscious on a piecemeal basis, as a result of internal or external *probing* which gives rise to a higher-order belief about the content in question. (Dennett himself sees this process as essentially linguistic, with both probes and higher-order thoughts being formulated in natural language. This variant of the view, although important in its own right, is not relevant to our present concerns.) This serves to convey to us the mere *illusion* of riches, because wherever we direct our attention, there we find a conscious perceptual content.

It is doubtful whether this sort of ‘fragmentist’ account can really explain the phenomenology of our experience, however. For it still faces the objection that the objects of attention can be immensely rich and varied at any given moment, hence requiring there to be an equally rich and varied repertoire of higher-order thoughts tokened at the same time. Think of immersing yourself in the colors and textures of a Van Gogh painting, for example, or the scene as you look out at your garden -- it would seem that one can be phenomenally conscious of a *highly* complex set of properties, which one could not even begin to describe or conceptualize in any detail. However, since the issues here are large and controversial, it

cannot yet be concluded that non-dispositionalist forms of higher-order thought theory have been decisively refuted.

5. Higher-Order Thought Theory (2): Dispositionalist

According to all forms of dispositionalist higher-order thought theory, the conscious status of an experience consists in its *availability* to higher-order thought (Dennett, 1978; Carruthers, 1996, 2000). As with the non-dispositionalist version of the theory, in its simplest form we have here a quite general proposal concerning the conscious status of any type of occurrent mental state, which becomes an account of phenomenal consciousness when the states in question are experiences (or images, emotions, etc.) with analog content. The proposal is this: a conscious mental event M, of mine, is one which is disposed to cause an activated belief (generally a non-conscious one) that I have M, and to cause it non-inferentially.

The proposal before us is therefore as follows:

> **Dispositionalist Higher-Order Thought Theory**:
> A phenomenally conscious mental state is a state with analog/non-conceptual intentional content, which is held in a special-purpose short-term memory store in such a way as to be available to cause (non-inferentially) higher-order thoughts about any of the contents of that store.

In contrast with the non-dispositionalist form of theory, the higher-order thoughts which render a percept conscious are not necessarily actual, but potential, on this account. So the objection now disappears, that an unbelievable amount of cognitive space would have to be taken up with every conscious experience. (There need not *actually* be *any* higher-order thought occurring, in order for a given perceptual state to count as phenomenally conscious, on this view.) So we can retain our belief in the rich and integrated nature of phenomenally conscious experience -- we just have to suppose that all of the contents in question are simultaneously *available* to higher-order thought. Nor will there be any problem in explaining why our faculty of higher-order thought should have evolved, nor why it should have access to perceptual contents in the first place -- this can be the standard sort of story in terms of Machiavellian intelligence.

It might well be wondered how their mere *availability* to higher-order thoughts could confer on our perceptual states the positive properties distinctive of phenomenal consciousness -- that is, of states having a *subjective* dimension, or a distinctive subjective *feel*. The answer may lie in the theory of content. Suppose that one agrees with Millikan (1984) that the representational content of a state depends, in part, upon the powers of the systems which *consume* that state. That is, suppose one thinks that *what* a state represents will depend, in part, on the kinds of inferences which the cognitive system is prepared to make in the presence of that state, or on the kinds of behavioral control which it can exert. In which case the presence of first-order perceptual representations to a consumer-system which can deploy a ‘theory of mind’, and which is capable of recognitional applications of theoretically-embedded concepts of experience, may be sufficient to render those representations *at the same time* as higher-order ones. This

would be what confers on our phenomenally conscious experiences the dimension of subjectivity. Each experience would at the same time (while also representing some state of the world, or of our own bodies) be a representation that we are undergoing just such an experience, by virtue of the powers of the 'theory of mind' consumer-system. Each percept of green, for example, would at one and the same time be an analog representation of *green* and an analog representation of *seems green* or *experience of green*. In fact, the attachment of a 'theory of mind' faculty to our perceptual systems may completely transform the contents of the latter's outputs.

(Consumer semantics embraces not only a number of different varieties of *teleosemantics*, but also various forms of *inferential role semantics*. For the former, see Millikan, 1984, 1986, 1989; and Papineau, 1987, 1993. For the latter, see Loar, 1981, 1982; McGinn, 1982, 1989; Block, 1986; and Peacocke, 1986, 1992.)

This account might seem to achieve all of the benefits of inner-sense theory, but without the associated costs. (Some potential draw-backs will be noted in a moment.) In particular, we can endorse the claim that phenomenal consciousness consists in a set of higher-order perceptions. This enables us to explain, not only the difference between conscious and non-conscious perception, but also how analog states come to acquire a subjective dimension or 'feel'. And we can also explain how it can be possible for us to acquire some purely recognitional concepts of experience (thus explaining the standard philosophical thought-experiments). But we don't have to appeal to the existence of any 'inner scanners' or organs of inner sense (together with their associated problems) in order to do this. Moreover, it should also be obvious why there can be no question of our higher-order contents getting out of line with their first-order counterparts, in such a way that one might be disposed to make recognitional judgments of *red* and *seems orange* at the same time. This is because the content of the higher-order experience is parasitic on the content of the first-order one, being formed from it by virtue of the latter's availability to a 'theory of mind' system.

On the down-side, the account isn't neutral on questions of semantic theory. On the contrary, it requires us to reject any form of pure input-semantics, in favor of some sort of consumer-semantics. We cannot then accept that intentional content reduces to informational content, nor that it can be explicated purely in terms of causal co-variance relations to the environment. So anyone who finds such views attractive will think that the account is a hard one to swallow. (For discussion of various different versions of input-semantics, see Dretske, 1981, 1986; Fodor, 1987, 1990; and Loewer and Rey, 1991.)

What will no doubt be seen by most people as the *biggest* difficulty with dispositionalist higher-order thought theory, however, is that it may have to deny phenomenal consciousness to most species of non-human animal. This objection will be discussed, among others, in the section following, since it can arguably also be raised against *any* form of higher-order theory.

6. Objections to a Higher-Order Approach

There have been a whole host of objections raised against higher-order theories of phenomenal

consciousness. (See, e.g., Aquila, 1990; Jamieson and Bekoff, 1992; Dretske, 1993, 1995; Goldman, 1993; Güzeldere, 1995; Tye, 1995; Chalmers, 1996; Byrne, 1997; Siewert, 1998.) Unfortunately, many of these objections, although perhaps intended as objections to higher-order theories as such, are often framed in terms of one or another particular version of such a theory. One general moral to be taken away from the present discussion should then be this: the different versions of a higher-order theory of phenomenal consciousness need to be kept distinct from one another, and critics should take care to state which version of the approach is under attack, or to frame objections which turn merely on the *higher-order character* of all of these approaches.

One generic objection is that higher-order theories, when combined with plausible empirical claims about the representational powers of non-human animals, will conflict with our common-sense intuition that such animals enjoy phenomenally conscious experience (Jamieson and Bekoff, 1992; Dretske, 1995; Tye, 1995). This objection can be pressed most forcefully against higher-order *thought* theories, of either variety; but it is also faced by inner-sense theory (depending on what account can be offered of the evolutionary function of organs of inner sense). Since there is considerable dispute as to whether even chimpanzees have the kind of sophisticated 'theory of mind' which would enable them to entertain thoughts about experiential states as such (Byrne and Whiten, 1988, 1998; Povinelli, 2000), it seems most implausible that many other species of mammal (let alone reptiles, birds and fish) would qualify as phenomenally conscious, on these accounts. Yet the intuition that such creatures enjoy phenomenally conscious experiences is a powerful and deep-seated one, for many people. (Witness Nagel's classic 1974 paper, which argues that there must be something which it is like to be a bat.)

The grounds for this common-sense intuition can be challenged, however. (How, after all, are we supposed to *know* whether it is like something to be a bat?) And that intuition can perhaps be explained away as a mere by-product of imaginative identification with the animal. (Since our *images* of their experiences are phenomenally conscious, we may naturally assume that the experiences *imaged* are similarly conscious. See Carruthers, 1999, 2000.) But there is no doubt that one crux of resistance to higher-order theories will lie here, for many people.

Another generic objection is that higher-order approaches cannot really *explain* the distinctive properties of phenomenal consciousness (Chalmers, 1996; Siewert, 1998). Whereas the argument from animals is that higher-order representations aren't *necessary* for phenomenal consciousness, the argument here is that such representations aren't *sufficient*. It is claimed, for example, that we can easily conceive of creatures who enjoy the postulated kinds of higher-order representation, related in the right sort of way to their first-order perceptual states, but where those creatures are wholly *lacking* in phenomenal consciousness.

In response to this objection, higher-order theorists will join forces with first-order theorists and others in claiming that these objectors pitch the standards for explaining phenomenal consciousness too high (Block and Stalnaker, 1999; Tye, 1999; Carruthers, 2000; Lycan, 2001). We will insist that a reductive explanation of something -- and of phenomenal consciousness in particular -- doesn't have to be such that we cannot conceive of the *explanandum* (that which is being explained) in the absence of the *explanans* (that which does the explaining). Rather, we just need to have good reason to think that the explained

properties are *constituted by* the explaining ones, in such a way that nothing *else* needed to be added to the world once the explaining properties were present, in order for the world to contain the target phenomenon. But this is hotly contested territory. And it is on this ground that the battle for phenomenal consciousness may ultimately be won or lost.

Animal Consciousness

There are the many reasons for philosophical interest in nonhuman animal (hereafter "animal") consciousness. First, if philosophy often begins with questions about the place of humans in nature, one way humans have attempted to locate themselves is by comparison and contrast with those things in nature most similar to themselves, i.e., other animals. Second, the problem of determining whether animals are conscious stretches the limits of knowledge and scientific methodology (beyond breaking point, according to some). Third, the question of whether animals are conscious beings or "mere automata", as Cartesians would have it, is of considerable moral significance given the dependence of modern societies on mass farming and the use of animals for biomedical research. Fourth, while theories of consciousness are frequently developed without special regard to questions about animal consciousness, the plausibility of such theories has sometimes been assessed against the results of their application to animal consciousness.

Questions about animal consciousness are just one corner of a more general set of questions about animal cognition and mind. The so-called "cognitive revolution" that took place during the latter half of the 20th century has led to many innovative experiments by comparative psychologists and ethologists probing the cognitive capacities of animals. Despite all this work, the topic of consciousness per se in animals has remained controversial, even taboo, among scientists, even while it remains a matter of common sense to most people that many other animals do have conscious experiences.

Concepts of Consciousness

In discussions of animal consciousness there is no clearly agreed upon sense in which the term "consciousness" is used. Having origins in folk psychology, "consciousness" has a multitude of uses that may not be resolvable into a single, coherent concept (Wilkes 1984). Nevertheless, several useful distinctions among different notions of consciousness have been made, and with the help of these distinctions it is possible to gain some clarity on the important questions that remain about animal consciousness.

Two ordinary senses of consciousness which are not in dispute when applied to animals are the sense of consciousness involved when a creature is awake rather than asleep, or in a coma, and the sense of consciousness implicated in the basic ability of organisms to perceive and thereby respond to selected features of their environments, thus making them conscious or aware of of those features. Consciousness in both these senses is identifiable in organisms belong to a wide variety of taxonomic groups.

There are two remaining senses of consciousness that cause controversy when applied to animals: *phenomenal consciousness* and *self-consciousness*.

Phenomenal consciousness refers to the qualitative, subjective, experiential, or phenomenological aspects of conscious experience, sometimes identified with qualia. (In this article I also use the term "sentience" to refer to phenomenal consciousness.) To contemplate animal consciousness in this sense is to consider the possibility that, in Nagel's (1974) phrase, there might be "something it is like" to be a member of another species. Nagel disputes our capacity to know, imagine, or describe in scientific (objective) terms *what* it is like to be a bat, but he assumes that there *is* something it is like. There are those, however, who would challenge this assumption directly. Others would less directly challenge the possibility of scientifically investigating its truth. Nevertheless, there is broad commonsense agreement that phenomenal consciousness is more likely in mammals and birds than it is in invertebrates, such as insects, crustaceans or molluscs (with the possible exception of some cephalopods), while reptiles, amphibians, and fish constitute an enormous grey area.

Self-consciousness refers to an organism's capacity for second-order representation of the organism's own mental states. Because of its second-order character ("thought about thought") the capacity for self consciousness is closely related to questions about "theory of mind" in nonhuman animals -- whether any animals are capable of attributing mental states to others. Questions about self-consciousness and theory of mind in animals are a matter of active scientific controversy, with the most attention focused on chimpanzees and to a more limited extent on the other great apes. As attested by this controversy (and unlike questions about animal sentience) questions about self-consciousness in animals are commonly regarded as tractable by empirical means.

The remainder of this article deals primarily with the attribution of consciousness in its phenomenal sense to animals, although there will be some discussion of self-consciousness and theory of mind in animals, in connection with arguments by Carruthers (1998a,b, 2000) that theory of mind is required for phenomenal consciousness.

Basic Questions: Epistemological and Ontological

The topic of consciousness in nonhuman animals has been primarily of epistemological interest to philosophers of mind. Two central questions are:

1. Can we know which animals beside humans are conscious? (The Distribution Question)
2. Can we know what, if anything, the experiences of animals are like? (The Phenomenological Question)

In his seminal paper "What is it like to be a bat?" Thomas Nagel (1974) simply assumes that there *is* something that it is like to be a bat, and focuses his attention on what he argues is the scientifically intractable problem of knowing what it is like. Nagel's confidence in the existence of conscious bat experiences would generally be held to be the commonsense view, but as we shall see, it is subject to challenge, and there are those who would argue that the Distribution Question is just as intractable as the Phenomenological Question.

The two questions might be seen as special cases of the general skeptical "problem of other minds", which even if intractable is nevertheless generally ignored to good effect by psychologists. However it is often thought that knowledge of animal minds -- what Allen & Bekoff (1997) refer to as "the other species of mind problem" -- presents special methodological problems because we cannot interrogate animals directly about their experiences (but see Sober 2000 for discussion of tractability within an evolutionary framework). Although there have been attempts to teach human-like languages to members of other species, none has reached a level of conversational ability that would solve this problem directly. Furthermore, except for some language-related work with parrots and dolphins, such approaches are generally limited to those animals most like ourselves, particularly the great apes. But there is great interest in possible forms of consciousness in a much wider variety of species than are suitable for such research, both in connection with questions about the ethical treatment of animals (e.g. Singer 1975/1990; Regan 1983; Rollin 1989; Varner 1999), and in connection with questions about the natural history of consciousness (Griffin 1976, 1984, 1992; Bekoff et al. 2002).

Griffin's agenda for the discipline he labeled "cognitive ethology" features the topic of animal consciousness and advocates a methodology based in naturalistic observations of animal behavior. This agenda has been strongly criticized, with his methodological suggestions often dismissed as anthropomorphic (see Bekoff & Allen 1997 for a survey). But such criticisms may have overestimated the dangers of anthropomorphism (Fisher 1990) and many of the critics themselves rely on claims for which there is scant scientific data (e.g. Kennedy 1992, who claims that the "sin" of anthropomorphism may be programmed into humans genetically).

While epistemological and related methodological issues have been at the forefront of discussions about animal consciousness, the main wave of recent philosophical attention to consciousness has been focused on ontological questions about the nature of phenomenal consciousness. One might reasonably think that the question of what consciousness is should be settled prior to tackling the Distribution Question -- that

ontology should drive the epistemology. In an ideal world this order of proceeding might be the preferred one, but as we shall see in the next section, the current state of disarray among the ontological theories makes such an approach untenable.

Applying Ontological Theories

Non-reductive accounts

Whether because they are traditional dualists, or because they think that consciousness is an as-yet-undescribed fundamental constituent of the physical universe, some philosophers maintain that consciousness is not explainable in familiar scientific terms. Such non-reductive accounts of consciousness (with the possible exception of those based in anthropocentric theology) provide no principled ontological reasons, however, for doubting that animals are conscious.

Cartesian dualism is, of course, traditionally associated with the view that animals lack minds. But Descartes' argument for this view was not based on any ontological principles, but upon what he took to be the failure of animals to use language conversationally or reason generally. On this basis he claimed that nothing in animal behavior requires a non-mechanical (mental) explanation; hence he saw no reason to attribute possession of mind to animals.

There is, however, no ontological reason why animal bodies are any less suitable vehicles for embodying a Cartesian mind than are human bodies. Hence dualism itself does not preclude animal minds. Similarly, more recent non-reductive accounts of consciousness in terms of fundamental properties are quite compatible with the idea of animal consciousness. None of these accounts provides any constitutional reason why those fundamental properties should not be located in animals. Furthermore, given that none of these theories specify empirical means for detecting the right stuff for consciousness, and indeed dualist theories *cannot* do so, they seem forced to rely upon behavioral criteria rather than ontological criteria for the deciding the Distribution Question.

Reductive accounts

Other philosophers have tried to give reductive accounts of consciousness in terms either of the physical, biochemical, or neurological properties of nervous systems (*physicalist* accounts) or in terms of other cognitive processes (*functionalist* accounts).

Physicalist accounts of consciousness, which identify consciousness with physical or physiological properties of neurons, do not provide any particular obstacles to attributing consciousness to animals, given that animals and humans share the same basic biology. Of course there is no consensus about which physical or neurological properties are to be identified with consciousness. But if it could be determined that phenomenal consciousness was identical to a property such as quantum coherence in the microtubules of neurons, or brain waves of a specific frequency, then settling the Distribution Question

would be a straightforward matter of establishing whether or not members of other species possess the specified properties.

Functionalist reductive accounts have sought to explain consciousness in terms of other cognitive processes. Some of these accounts identify phenomenal consciousness with the (first-order) representational properties of mental states. Such accounts are generally quite friendly to attributions of consciousness to animals, for it is relatively uncontroversial that animals have internal states that have the requisite representational properties. Such a view underlies Dretske's (1995) claim that phenomenal consciousness is inseparable from a creature's capacity to perceive and respond to features of its environment, i.e., one of the uncontroversial senses of consciousness identified above. On Dretske's view, phenomenal consciousness is therefore very widespread in the animal kingdom. Likewise, Tye (2000) argues, based upon his first-order representational account of phenomenal consciousness, that it extends even to honeybees.

Functionalist theories of phenomenal consciousness that rely on more elaborately structured cognitive capacities can be less accommodating to the belief that animals do have conscious mental states. For example, some twentieth century philosophers, while rejecting Cartesian dualism, have turned his epistemological reliance upon language as an indicator of consciousness into an ontological point about the essential involvement of linguistic processing in human consciousness. Such insistence on the importance of language for consciousness underwrites the tendency of philosophers such as Dennett (1969, 1995, 1997) to deny that animals are conscious in anything like the same sense that humans are (see also Carruthers 1996).

Because Carruthers has explicitly applied his functionalist "higher order thought" theory of phenomenal consciousness to derive a negative conclusion about animal consciousness (Carruthers 1998a,b, 2000) this account deserves special attention here. According to Carruthers, a mental state is conscious for a subject just in case it is available to be thought about directly by that subject. Furthermore, according to Carruthers, such higher-order thoughts are not possible unless a creature has a "theory of mind" to provide it with the concepts necessary for thought about mental states. But, Carruthers argues, there is little, if any, scientific support for theory of mind in nonhuman animals, even among the great apes, so he concludes that there is little support either for the view that any animals possess phenomenological consciousness. The evaluation of this argument will be taken up further below, but it is worth noting here that since most developmental psychologists agree that young children before the age of 4 lack a theory of mind, Carruthers' view entails that they are not sentient either -- fear of needles notwithstanding! This is a bullet Carruthers bites, although for many it constitutes a *reductio* of his view (a response Carruthers would certainly regard as question-begging).

In contrast to Carruthers' higher-order *thought* account of sentience, other theorists such as Armstrong (1980), and Lycan (1996) have preferred a higher-order *experience* account, where consciousness is explained in terms of inner perception of mental states, a view that can be traced back to Aristotle, and also to John Locke. Because such models do not require the ability to conceptualize mental states, proponents of higher-order experience theories have been slightly more inclined than higher-order theorists to allow that such abilities may be found in other animals[1].

Phenomenal consciousness is just one feature (some would say the defining feature) of mental states or events. Any theory of animal consciousness must be understood, however, in the context of a larger investigation of animal cognition that (among philosophers) will also be concerned with issues such as intentionality (in the sense described by the 19th C. German psychologist Franz Brentano) and mental content (Dennett 1983, 1987; Allen 1992a,b, 1995, 1997).

Philosophical opinion divides over the relation of consciousness to intentionality with some philosophers maintaining that they are strictly independent, others (particularly proponents of the functionalist theories of consciousness described in this section) arguing that intentionality is necessary for consciousness, and still others arguing that consciousness is necessary for genuine intentionality (see Allen 1997 for discussion). Many behavioral scientists accept cognitivist explanations of animal behavior that attribute representational states to their subjects. Yet they remain hesitant to attribute consciousness. If the representations invoked within cognitive science are intentional in Brentano's sense, then these scientists seem committed to denying that consciousness is necessary for intentionality.

Limits of ontology

There remains great uncertainty about the ontological status of consciousness. It is beyond the scope of this article to survey the strong attacks that have been mounted against the various accounts of consciousness, but it is safe to say that none of them seems secure enough to hang a decisive endorsement or denial of animal consciousness upon it. Accounts of consciousness in terms of basic neurophysiological properties, the quantum-mechanical properties of neurons, or *sui generis* properties of the universe are just as insecure as the various functionalist accounts. And even those ontological accounts that are, in general outline, compatible with animal sentience are not specific enough to permit ready answers to the Distribution Question. Hence no firm conclusions about the distribution of consciousness can be drawn on the basis of the work to date by philosophers on the ontology of consciousness.

Where does this leave the epistemological questions about animal consciousness? While it may seem natural to think that we must have a theory of what consciousness is before we try to determine whether other animals have it, this may in fact be putting the conceptual cart before the empirical horse. In the early stages of the scientific investigation of any phenomenon, putative samples must be identified by rough rules of thumb (or working definitions) rather than complete theories. Early scientists identified gold by contingent characteristics rather than its atomic essence, knowledge of which had to await thorough investigation of many putative examples -- some of which turned out to be gold and some not. Likewise, at this stage of the game, perhaps the study of animal consciousness would benefit from the identification of animal traits worthy of further investigation, with no firm commitment to idea that all these examples will involve conscious experience.

Of course, as a part of this process some reasons must be given for identifying specific animal traits as "interesting" for the study of consciousness, and in a weak sense such reasons will constitute an argument

for attributing consciousness to the animals possessing those traits. These reasons can be evaluated even in the absence of an accepted ontology for consciousness. Furthermore, those who would bring animal consciousness into the scientific fold in this way must also explain how scientific methodology is adequate to the task in the face of various arguments that it is inadequate. These arguments, and the response to them, can also be evaluated in the absence of ontological certitude. Thus there is plenty to cover in the remaining sections of this encyclopedia entry.

Evaluation of Arguments Against Animal Consciousness

Dissimilarity arguments

Recall the Cartesian argument from the previous section against animal consciousness (or animal mind) on the grounds that animals do not use language conversationally or reason generally. This argument, based on the alleged failure of animals to display certain intellectual capacities, is illustrative of a general pattern of using certain *dissimilarities* between animals and humans to argue that animals lack consciousness.

A common refrain in response to such arguments is that, in situations of partial information, "absence of evidence is not evidence of absence". Descartes dismissed parrots vocalizing human words because he thought it was merely meaningless repetition. This judgement may have been appropriate for the few parrots he encountered, but it was not based on a systematic, scientific investigation of the capacities of parrots. Nowadays many would argue that Pepperberg's study of the African Grey parrot "Alex" (Pepperberg 1999) should lay the Cartesian prejudice to rest. This study, along with several on the acquisition of a degree of linguistic competence by chimpanzees (e.g., Gardner et al. 1989; Savage-Rumbaugh 1996) would seem to undermine Descartes' assertions about lack of conversational language use and general reasoning abilities in animals.

Cartesians respond by pointing out the limitations shown by animals in such studies (they can't play a good game of chess, after all), and they join linguists in protesting that the subjects of animal-language studies have not fully mastered the recursive syntax of natural human languages. But this kind of post hoc raising of the bar suggests to many scientists that the Cartesian position is not being held as a scientific hypothesis, but as a dogma to be defended by any means. Nevertheless, dissimilarity arguments are not entirely powerless to give some pause to defenders of animal sentience, for surely most would agree that, at some point, the dissimilarities between the capacities of humans and the members of another species (the common earthworm *Lumbricus terrestris*, for example) are so great that it is unlikely that such creatures are sentient. A grey area arises precisely because no one can say how much dissimilarity is enough to trigger the judgement that sentience is absent.

Similarity arguments

A different kind of strategy that has been used to deny animal consciousness is to focus on certain *similarities* between animal behaviors and behaviors which may be conducted *un*consciously by humans. Thus, for example, Carruthers (1989, 1992) argued that *all* animal behavior can be assimilated to the non-conscious activities of humans, such as driving while distracted ("on autopilot"), or to the capacities of "blindsight" patients whose damage to visual cortex leaves them phenomenologically blind in a portion of their visual fields (a "scotoma") but nonetheless able to identify things presented to the scotoma. (He refers to both of these as examples of "unconscious experiences".)

This comparison of animal behavior to the unconscious capacities of humans can be criticized on the grounds that, like Descartes' pronouncements on parrots, it is based only on unsystematic observation of animal behavior. There are grounds for thinking that careful investigation would reveal that there is not a very close analogy between animal behavior and human behaviors associated with these putative cases of unconscious experience. For instance, it is notable that the unconscious experiences of automatic driving are not remembered by their subjects, whereas there is no evidence that animals are similarly unable to recall their allegedly unconscious experiences. Likewise, blindsight subjects do not spontaneously respond to things presented to their scotomas, but must be trained to make responses using a forced-response paradigm. There is no evidence that such limitations are normal for animals, or that animals behave like blindsight victims with respect to their visual experiences (Jamieson & Bekoff 1991).

Carruthers' argument from the absence of self-consciousness and theory of mind

In his more recent publications, Carruthers (1998a,b, 2000) appears to have moved on from the similarity argument of the previous section, now placing more stock in the argument based on his higher order thought theory that was described above. Recall that according to this argument, phenomenal consciousness requires the capacity to think about, and therefore conceptualize, one's own thoughts.[2] Such conceptualization requires, according to Carruthers, a theory of mind. And, Carruthers maintains, there is little basis for thinking that any nonhuman animals have a theory of mind, with the possible exception of chimpanzees. This argument is, of course, no stronger than the higher-order thought account of consciousness upon which it is based. But setting that aside for the sake of argument, this challenge by Carruthers deserves further attention as perhaps the most empirically-detailed case against animal consciousness to have been made in the philosophical literature.

The systematic study of self-consciousness and theory of mind in nonhuman animals has its roots in an approach to the study of self-consciousness pioneered by Gallup (1970). It was long known that chimpanzees would use mirrors to inspect their images, but Gallup developed a protocol that appears to allow a scientific determination of whether it is merely the mirror image *per se* that is the object of interest to the animal inspecting it, or whether it is the image qua proxy for the animal itself that is the object of interest. Using chimpanzees with extensive prior familiarity with mirrors, Gallup anesthetized his subjects and marked their foreheads with a distinctive dye, or, in a control group, anesthetized them only. Upon waking, marked animals who were allowed to see themselves in a mirror touched their own foreheads in the region of the mark significantly more frequently than controls who were either unmarked

or not allowed to look into a mirror. Gallup's protocol has been repeated with other great apes and some monkey species, but besides chimpanzees only orang utans consistently "pass" the test. Using a modified version of Gallup's procedure, involving no anesthesia, Reiss & Marino (2001) have recently produced evidence of mirror self-recognition in bottlenose dolphins.

According to Gallup et al. (2002) "Mirror self-recognition is an indicator of self-awareness." Furthermore, he claims that "the ability to infer the existence of mental states in others (known as theory of mind, or mental state attribution) is a byproduct of being self-aware." He describes the connection between self-awareness and theory of mind thus: "If you are self-aware then you are in a position to use your experience to model the existence of comparable processes in others." The success of chimpanzees on the mirror self-recognition task thus may give some reason to maintain that they are phenomenally conscious on Carruthers' account, whereas the failure of most species that have been tested to pass the test might be taken as evidence against their sentience.

Carruthers neither endorses nor outright rejects the conclusion that chimpanzees are sentient. His suspicion that even chimpanzees might lack theory of mind, and therefore (on his view) phenomenal consciousness, is based on some ingenious laboratory studies by Povinelli (1996) showing that in interactions with human food providers, chimpanzees apparently fail to understand the role of eyes in providing visual information to the humans, despite their outwardly similar behavior to humans in attending to cues such as facial orientation. The interpretation of Povinelli's work remains controversial. Hare et al. (2000) conducted experiments in which dominant and subordinate animals competed with each other for food, and concluded that "at least in some situations chimpanzees know what conspecifics do and do not see and, furthermore, that they use this knowledge to formulate their behavioral strategies in food competition situations." They suggest that Povinelli's negative results may be due to the fact that his experiments involve less natural chimp-human interactions. Given the uncertainty, Carruthers is therefore well-advised in the tentative manner in which he puts forward his claims about chimpanzee sentience.

A full discussion of the controversy over theory of mind deserves an entry of its own (see also Heyes 1998), but it is worth remarking here that the theory of mind debate has origins in the hypothesis that primate intelligence in general, and human intelligence in particular, is specially adapted for social cognition (see Byrne & Whiten 1988, especially the first two chapters, by Jolly and Humphrey). Consequently, it has been argued that evidence for the ability to attribute mental states in a wide range of species might be better sought in natural activities such as social play, rather than in laboratory designed experiments which place the animals in artificial situations (Allen & Bekoff 1997; see esp. chapter 6; see also Hare et al. 2000, Hare et al. 2001, and Hare & Wrangham 2002). Furthermore, to reiterate the maxim that absence of evidence is not evidence of absence, it is quite possible that the mirror test is not an appropriate test for theory of mind in most species because of its specific dependence on the ability to match motor to visual information, a skill that may not have needed to evolve in a majority of species. Alternative approaches that have attempted to provide strong evidence of theory of mind in nonhuman animals under natural conditions have generally failed to produce such evidence (see, e.g., the conclusions about theory of mind in vervet monkeys by Cheney & Seyfarth 1990), although anecdotal evidence tantalizingly suggests that researchers still have not managed to devise the right experiments.

Methodological arguments

Many scientists remain convinced that even if questions about self-consciousness are empirically tractable, no amount of experimentation can provide access to phenomenal consciousness in nonhuman animals. This remains true even among those scientists who are willing to invoke cognitive explanations of animal behavior that advert to internal representations. Opposition to dealing with consciousness can be understood as a legacy of behavioristic psychology first because of the behaviorists' rejection of terms for unobservables unless they could be formally defined, and second because of the strong association in many behaviorists' minds between the use of mentalistic terms and the twin bugaboos of Cartesian dualism and introspectionist psychology (Bekoff & Allen 1997). In some cases these scientists are even dualists themselves, but they are strongly committed to denying the possibility of scientifically investigating consciousness, and remain skeptical of all attempts to bring it into the scientific mainstream.

It is worth remarking that there is often a considerable disconnect between philosophers and psychologists (or ethologists) on the topic of animal minds. Some of this can be explained by the failure of some psychologists to heed the philosophers' distinction between intentionality in its ordinary sense and intentionality in the technical sense derived from Brentano (with perhaps most of the blame being apportioned to philosophers for failing to give clear explanations of this distinction and its importance). Indeed, some pscyhologists, having conflated Brentano's notion with the ordinary sense of intentionality, and then identifying the ordinary sense of intentionality with "free will" and conscious deliberation, have literally gone on to substitute the term "consciousness" in their criticisms of philosophers who were discussing the intentionality of animal mental states and who were not explicitly concerned with consciousness at all (see, e.g., Blumberg & Wasserman 1995).

Because consciousness is assumed to be private or subjective, it is often taken to be beyond the reach of objective scientific methods (see Nagel 1974). This claim might be taken in either of two ways. On the one hand it might be taken to bear on the possibility of answering the Distribution Question, i.e. to reject the possibility of knowledge that a member of another taxonomic group (e.g. a bat) has conscious states. On the other hand it might be taken to bear on the possibility of answering the Phenomenological Question, i.e. to reject the possibility of knowledge of the phenomenological details of the mental states of a member of another taxonomic group. The difference between believing with justification *that* a bat is conscious and knowing *what* it is like to be a bat is important because, at best, the privacy of conscious experience supports a negative conclusion only about the latter. To support a negative conclusion about the former one must also assume that consciousness has absolutely no measurable effects on behavior, i.e. one must accept epiphenomenalism. But if one rejects epiphenomenalism and maintains that consciousness does have effects on behavior then a strategy of inference to the best explanation may be used to support its attribution. More will be said about this in the next section.

Evaluation of Arguments For Animal

Consciousness

Similarity arguments

Most people, if asked why they think familiar animals such as their pets are conscious would point to similarities between the behavior of those animals and human behavior. Similarity arguments for animal consciousness thus have roots in common sense observations. But they may also be bolstered by scientific investigations of behavior and neurology as well as considerations of evolutionary continuity (homology) between species. Nagel's own confidence in the existence of phenomenally conscious bat experiences is based on nothing more than this kind of reliance on shared mammalian traits (Nagel 1974).

Many judgements of the similarity between human and animal behavior are readily made by ordinary observers. The reactions of many animals, particularly other mammals, to bodily events that humans would report as painful are easily and automatically recognized by most people as pain responses. High-pitched vocalizations, fear responses, nursing of injuries, and learned avoidance are among the responses to noxious stimuli that are all part of the common mammalian heritage. Similar responses are also visible to some degree or other in organisms from other taxonomic groups.

Less accessible to casual observation, but still in the realm of behavioral evidence are scientific demonstrations that members of other species, even of other phyla, are susceptible to the same visual illusions as we are (e.g. Fujita et al. 1991) suggesting that their visual experiences are similar.

Neurological similarities between humans and other animals are also been taken to suggest commonality of conscious experience. All mammals share the same basic brain anatomy, and much is shared with vertebrates more generally. A large amount of scientific research that is of direct relevance to the treatment of human pain, including on the efficacy of analgesics and anesthetics, is conducted on rats and other animals. The validity of this research depends on the similar mechanisms involved[3] and to many it seems arbitrary to deny that injured rats, who respond well to opiates for example, feel pain[4]. Likewise, much of the basic research that is of direct relevance to understanding human visual consciousness has been conducted on the very similar visual systems of monkeys. Monkeys whose primary visual cortex is damaged even show impairments analogous to those of human blindsight patients (Stoerig & Cowey 1997) suggesting that the visual consciousness of intact monkeys is similar to that of intact humans.

Such similarity arguments are, of course, inherently weak for it is always open to critics to exploit some *dis*analogy between animals and humans to argue that the similarities don't entail the conclusion that both are sentient (Allen 1998). Even when bolstered by evolutionary considerations of continuity between the species, the arguments are vulnerable, for the mere fact that humans have a trait does not entail that our closest relatives must have that trait too. There is no inconsistency with evolutionary continuity to maintain that only humans have the capacity to learn to play chess. Likewise for consciousness. Povinelli & Giambrone (2000) also argue that the argument from analogy fails because superficial observation of quite similar behaviors even in closely related species does not guarantee that the underlying cognitive

principles are the same, a point that Povinelli believes is demonstrated by his research described in the previous section, into how chimpanzees use cues to track visual attention (Povinelli 1996).

Perhaps a combination of behavioral, physiological and morphological similarities with evolutionary theory amounts to a stronger overall case[5]. But in the absence of more specific theoretical grounds for attributing consciousness to animals, this composite argument -- which might be called "the argument from homology" -- despite its comportment with common sense, is unlikely to change the minds of those who are skeptical.

Inference to the best explanation

One way to get beyond the weaknesses in the similarity arguments is to try to articulate a theoretical basis for connecting the observable characteristics of animals (behavioral or neurological) to consciousness. As mentioned above, one approach to bringing consciousness into the scientific fold is to try identify behaviors for which it seems that an explanation in terms of mechanisms involving consciousness might be justified over unconscious mechanisms by a strategy of inference to the best explanation. This form of inference would be strengthened by a good understanding of the biological function or functions of consciousness. If one knew what phenomenal conscious is *for* then one could exploit that knowledge to infer its presence in cases where that function is fulfilled, so long as other kinds of explanations can be shown less satisfactory.

If phenomenal consciousness is completely epiphenomenal, as some philosophers believe, then a search for the functions of consciousness is doomed to futility. In fact, if consciousness is completely epiphenomenal then it cannot have evolved by natural selection. On the assumption that phenomenal consciousness is an evolved characteristic of human minds, at least, and therefore that epiphenomenalism is false, then an attempt to understand the biological functions of consciousness may provide the best chance of identifying its occurrence in different species.

Such an approach is nascent in Griffin's attempts to force ethologists to pay attention to questions about animal consciousness. (For the purposes of this discussion I assume that Griffin's proposals are intended to relate to phenomenal consciousness, as well, perhaps, to consciousness in its other senses.) In a series of books, Griffin (who made his scientific reputation by carefully detailing the physical and physiological characteristics of echolocation by bats) provides examples of communicative and problem-solving behavior by animals, particularly under natural conditions, and argues that these are prime places for ethologists to begin their investigations of animal consciousness (Griffin 1976, 1984, 1992).

Although he thinks that the intelligence displayed by these examples suggests conscious thought, many critics have been disappointed by the lack of systematic connection between Griffin's examples and the attribution of consciousness (see Alcock 1992; Bekoff & Allen 1996; Allen & Bekoff 1997). Griffin's main positive proposal in this respect has been the rather implausible suggestion that consciousness might have the function of compensating for limited neural machinery. Thus Griffin is motivated to suggest that consciousness may be more important to honey bees than to humans.

If compensating for small sets of neurons is not a plausible function for consciousness, what might be? The commonsensical answer would be that consciousness "tells" the organism about events in the environment, or, in the case of pain and other proprioceptive sensations, about the state of the body. But this answer begs the question against opponents of attributing conscious states to animals for it fails to respect the distinction between phenomenal consciousness and mere awareness (in the uncontroversial sense of detection) of environmental or bodily events. Opponents of attributing the phenomenal consciousness to animals are not committed to denying the more general kind of consciousness *of* various external and bodily events, so there is no logical entailment from awareness of things in the environment or the body to animal sentience.

Perhaps more sophisticated attempts to spell out the functions of consciousness are similarly doomed. But Allen & Bekoff (1997, ch. 8) suggest that progress might be made by investigating the capacities of animals to adjust to their own perceptual errors. Not all adjustments to error provide grounds for suspecting that consciousness is involved, but in cases where an organism can adjust to a perceptual error while retaining the capacity to exploit the content of the erroneous perception, then there may be a robust sense in which the animal internally distinguishes its own appearance states from other judgements about the world. (Humans, for instance, have conscious visual experiences that they know are misleading -- i.e., visual illusions -- yet they can exploit the erroneous content of these experiences for various purposes, such as deceiving others or answering questions about how things *appear* to them.) Given that there are theoretical grounds for identifying conscious experiences with "appearance states", attempts to discover whether animals have such capacities might be a good place to start looking for animal consciousness. It is important, however, to emphasize that such capacities are not themselves intended to be definitive or in any way criterial for consciousness.

Carruthers (2000) makes a similar suggestion about the function of consciousness, relating it to the general capacity for making an appearance-reality distinction; of course he continues to maintain that this capacity depends upon having conceptual resources that are beyond the grasp of nonhuman animals.

Summary

An article such as this perhaps raises more questions than it answers, but the topic would be of little philosophical interest if it were otherwise.

To philosophers interested in animal welfare or animal rights the issue of animal sentience is of utmost importance. This is due to wide, but by no means universal, acceptance of the biconditional statement [A]: animals deserve moral consideration if and only if they are sentient (especially possessing the capacity to feel pain). Some philosophers have defended the view that animals are not sentient and attempted to use one of [A]'s component conditionals for *modus tollens*. Indeed Carruthers (1989) even argued that given their lack of sentience, it would be immoral *not* to use animals for research and other experimentation if doing so would improve the lot of sentient creatures such as ourselves. He has more recently backed off this view (1998b), denying [A] by claiming that sentience is not the sole basis for

moral consideration, and that animals qualify for consideration on the basis of frustration of their *unconscious* desires. Varner (1999) disagrees with Carruthers by arguing for conscious desires throughout mammals and birds, but like Carruthers he also rejects [A], arguing for an even more inclusive criterion of moral considerability in terms of the biological "interests" that all living things have.

Others are inclined to use the other component conditional of [A] for *modus ponens*, taking for granted that animals are conscious, and regarding any theory of consciousness which denies this as defective. In this connection it is also sometimes argued that if there is uncertainty about whether other animals really are conscious, the morally safe position is to give them the benefit of the doubt.

The fact remains that for most philosophers of mind, the topic of animal consciousness is of peripheral interest to their main project of understanding the ontology of consciousness. Because of their focus on ontological rather than epistemological issues, there is often quite a disconnect between philosophers and scientists on these issues. But there are encouraging signs that interdisciplinary work between philosophers and behavioral scientists is beginning to lay the groundwork for addressing some questions about animal consciousness in a philosophically sophisticated yet empirically tractable way.

Stanford Encyclopedia of Philosophy
Notes to Animal Consciousness

Notes

1. The evidence for this is somewhat ambiguous, however. For example, Güven Güzeldere (1995) reports private correspondence from David Armstrong who wrote:

> ... following Locke and Kant, I think the introspective awareness is perception-like. For instance, it is very like proprioception, and seems not to involve any linguistic capacity. Perhaps chimpanzees and even dogs have such consciousness." [G. Güzeldere (1995, fn. 22): "Is consciousness the perception of what passes in one's own mind?" In *Conscious Experience* ed. Thomas Metzinger. Paderborn: Schöningh/Imprint Academic, 1995, fn. 22.]

And Lycan, commenting on Carruthers (1998a) in his contribution to the *Psyche* symposium on animal consciousness writes:

> Even if I am right about human beings, of course it does not follow that other animals exhibit a comparable degree of computational complexity. Perhaps some do and some do not; perhaps few if any do. I would continue to maintain that an animal has phenomenal-consciousness in the strong sense if and only if that animal has HOEs [Higher Order Experiences]. So I would at least provisionally conclude that if many animals (including very young human children) lack the computational complexity needed for HOEs, those same many animals lack phenomenal-consciousness in the strong sense. Carruthers would not disagree with that.

These are hardly ringing endorsements by higher-order experience theorists for animal consciousness.

2. This argument is very reminiscent of Davidson's (1975) argument against animal thought on the grounds that one must have the concept of thought to be able to think. I am not aware that Davidson was ever tempted to turn this into an argument against animal sentience.

3. See Varner (1999, pp. 51-54) for a discussion of the phylogenetic distribution of the mechanisms underlying pain. However, caution is recommended with respect to his table on p. 53 which suggests that the presence of specialized nociceptive neurons is limited to vertebrates. The existence of nociceptors seems to be well established in marine molluscs. (See E. T. Walters [1992] "Possible clues about the evolution of hyperalgesia from mechanisms of nociceptive sensitization in *aplysia*." In *Hyperalgesia and Allodynia* ed.W. D. Willis Jr. New York: Raven Press.)

4. While the locution "feel pain" suggests conscious experience to most readers, it does not do so for all. For instance, Carruthers (1998b) maintains that although animals do in fact feel pain, they do not feel pain *consciously* - or, as Carruthers somewhat paradoxically puts it, he denies that the feeling feels like anything. Many philosophers would, however, charge that the concept of an unconscious pain is conceptually incoherent, pain being *essentially* conscious.

5. Because of the importance of animal sentience to ethics, some of the most explicit statements of the evolution-reinforced similarity argument can be found in the animal rights and animal welfare literature (e.g., Singer 1975/1990; Regan 1983; Andrews 1996; Varner 1999).

Behaviorism

It has sometimes been said that "behave is what organisms do." Behaviorism is built on this assumption, and its goal is to promote the scientific study of behavior.

In this entry I consider different types of behaviorism. I outline reasons for and against being a behaviorist. I consider contributions of behaviorism to the study of behavior. Special attention is given to the so-called "radical behaviorism" of B. F. Skinner (1904-90).

What is Behaviorism?

Behaviorism is a doctrine, or set of doctrines, about human and nonhuman animal behavior. Behaviorism is committed in its fullest and most complete sense to the truth of the following three sets of claims.

> (1) Psychology is the science of behavior. Psychology is not the science of mind.
>
> (2) Behavior can be described and explained without making reference to mental events or to internal psychological processes. The sources of behavior are external (in the environment), not internal (in the mind).

> (3) In the course of theory development in psychology, if, somehow, mental terms or concepts are deployed in describing or explaining behavior, then either (a) these terms or concepts should be eliminated and replaced by behavioral terms or (b) they can and should be translated or paraphrased into behavioral concepts.

The three sets of claims are logically distinct. Moreover, taken independently, each helps to form a type of behaviorism. "Methodological" behaviorism is committed to the truth of (1). "Psychological" behaviorism is committed to the truth of (2). "Analytical" behaviorism (also known as "philosophical" or "logical" behaviorism) is committed to the truth of the statement in (3) that mental terms or concepts can and should be translated into behavioral concepts.

Other nomenclature is sometimes used to classify behaviorisms. Georges Rey (1997, p. 96), for example, classifies behaviorisms as methodological, analytical, and radical, where "radical" is Rey's term for what I am classifying as psychological behaviorism. I reserve the term "radical" for the psychological behaviorism of B. F. Skinner. Skinner employs the expression "radical behaviorism" to describe his brand of behaviorism or his philosophy of behaviorism (see Skinner 1976, p. 18). In my classification scheme, radical behaviorism is a sub-type of psychological behaviorism, primarily, although it combines all three types of behaviorism (methodological, analytical, and psychological).

Three Types of Behaviorism

Methodological behaviorism is a normative theory about the scientific conduct of psychology. It claims that psychology should concern itself with the behavior of organisms (human and nonhuman animals). Psychology should not concern itself with mental states or events or with constructing internal information processing accounts of behavior. According to methodological behaviorism, reference to mental events (such as an animal's beliefs or desires) adds nothing to what psychology can and should understand about the sources of behavior. Mental events are private entities which, given the necessary publicity of science, do not form proper objects of empirical study. Methodological behaviorism is a dominant theme in the writings of John Watson (1878-1958).

Psychological behaviorism is a research program within psychology. It purports to explain human and animal behavior in terms of external physical stimuli, responses, learning histories, and (for certain types of behavior) reinforcements. Psychological behaviorism is present in the work of Ivan Pavlov (1849-1936), Edward Thorndike (1874-1949), as well as Watson. Its fullest and most influential expression is B. F. Skinner's (1904-90) work on schedules of reinforcement.

To illustrate, consider a food-deprived rat in an experimental chamber. If a particular movement, such as pressing a lever when a light is on, is followed by the presentation of food, then the likelihood of the rat's pressing the lever when hungry, again, and the light is on, is increased. Such presentations are reinforcements, such lights are (discriminative) stimuli, such lever pressings are responses, and such trials or associations are learning histories.

Analytical behaviorism is a theory within philosophy about the meaning or semantics of mental terms or concepts. It says that the very notion of a mental state or condition is the notion of a behavioral disposition or family of behavioral tendencies. When we attribute a belief to someone, for example, we are not saying that he or she is in a particular internal state or condition. Instead, we are characterizing the person in terms of what he or she might do in particular situations. Analytical behaviorism may be found in the work of Gilbert Ryle (1900-76) and the later work of Ludwig Wittgenstein (1889-51).

Roots of Behaviorism

Each of methodological, psychological, and analytical behaviorism has historical foundations. Analytical behaviorism traces its historical roots to the philosophical movement known as Logical Positivism (see Smith 1986). Logical positivism proposes that the meaning of sentences used in science be understood in terms of the experimental conditions or observations that verify their truth. This positivist doctrine is known as "verificationism". In psychology, verificationism grounds analytical behaviorism, namely, the claim that mental concepts refer to behavioral tendencies and so must be translated into behavioral terms.

Analytical behaviorism helps to avoid substance dualism. Substance dualism is the doctrine that mental states take place in a special, non-physical mental substance (the immaterial mind). By contrast, for analytical behaviorism the belief that I have in, for example, arriving on time for a 2pm dental appointment, believing that I have a 2pm appointment, is not the property of a mental substance. Believing is a family of tendencies of my body. We cannot identify the belief independently of my arrival or other members of the family. So, we cannot treat it as the cause of the arrival.

Psychological behaviorism's historical roots consist, in part, in the classical associationism of the British Empiricists, foremost John Locke (1632-1704) and David Hume (1711-76). According to classical associationism, intelligent behavior is the product of associative learning. As a result of associations or pairings between perceptual experiences or stimulations on the one hand, and ideas or thoughts on the other, persons and animals acquire knowledge of their environment and how to act. Associations enable creatures to discover the causal structure of the world. Association is most helpfully viewed as the acquisition of knowledge about relations between events. Intelligence in behavior is a mark of such knowledge.

Classical associationism relied on introspectible entities, such as perceptual experiences or stimulations as the first links in associations, and thoughts or ideas as the second links. Psychological behaviorism, motivated by experimental interests, claims that to understand the origins of behavior, reference to stimulations (experiences) should be replaced by reference to stimuli (physical events in the environment), and that reference to thoughts or ideas should be eliminated or displaced in favor of reference to responses (overt behavior). Psychological behaviorism is associationism without appeal to mental events.

Don't human beings talk of introspectible entities even if these are not recognized by behaviorism?

Psychological behaviorists regard the practice of talking about one's own states of mind, and of introspectively reporting those states, as potentially useful data in psychological experiments, but as not presupposing the metaphysical subjectivity or non-physical presence of those states. There are different sorts of causes behind introspective reports, and psychological behaviorists take these to be amenable to behavioral analysis. (See, by comparison, Dennett's method of heterophenomenology; Dennett 1991, pp. 72-81).

The task of psychological behaviorism is to specify types of association, understand how environmental events control behavior, discover and elucidate causal regularities or laws which govern the formation of associations, and predict how behavior will change as the environment changes. The word "conditioning" is commonly used to specify the process involved in acquiring new associations. Animals in so-called "operant" conditioning experiments are not learning to, for example, press levers. Instead, they are learning about the relationship between events in their environment, for example, that a particular behavior, pressing the lever, causes food to appear.

In its historical foundations, methodological behaviorism shares with analytical behaviorism the influence of positivism. One of the goals of positivism was to unify psychology with natural science. Watson wrote that "psychology as a behaviorist views it is a purely objective experimental branch of natural science. Its theoretical goal is . . . prediction and control" (1913, p. 158). Watson also wrote of the purpose of psychology as follows: "To predict, given the stimulus, what reaction will take place; or, given the reaction, state what the situation or stimulus is that has caused the reaction" (1930, p. 11).

Though logically distinct, methodological, psychological, and analytical behaviorisms often are found in one behaviorism. Skinner's radical behaviorism combines all three forms of behaviorism. It follows analytical strictures (at least loosely) in paraphrasing mental terms behaviorally, when or if they cannot be eliminated from explanatory discourse. In Verbal Behavior (1957) and elsewhere, Skinner tries to show how mental terms can be given behavioral interpretations. In About Behaviorism (1976) he says that when mental terminology cannot be eliminated it can be "translated into behavior" (p. 18, Skinner brackets the expression with his own double quotes).

Radical behaviorism is concerned with the behavior of organisms, not with internal processing. So, it is a form of methodological behaviorism. Finally, radical behaviorism understands behavior as a reflection of frequency effects among stimuli, which means that it is a form of psychological behaviorism.

Popularity of Behaviorism

Behaviorism of one sort or another was an immensely popular research program or methodological commitment among students of behavior from about the second decade of the twentieth century through its middle decade (see Bechtel, Abrahamsen, and Graham, 1998, pp. 15-17). In addition to Ryle and Wittgenstein, philosophers with sympathies for behaviorism included Carnap (1932-33), Hempel (1949), and Quine (1960). Quine, for example, took a behaviorist approach to the study of language. Quine claimed that the notion of psychological or mental activity has no place in a scientific account of either

the origins or the meaning of speech. To talk in a scientifically disciplined manner about the meaning of an utterance is to talk about stimuli for the utterance, its so-called "stimulus meaning". Hempel (1949) claimed that "all psychological statements that are meaningful . . . are translatable into statements that do not involve psychological concepts," but only concepts for physical behavior (p. 18).

Among psychologists behaviorism was even more popular than among philosophers. In addition to Pavlov, Skinner, Thorndike, and Watson, the list of behaviorists among psychologists included, among others, E. C. Tolman (1886-1959), C. L. Hull (1884-52), and E. R. Guthrie (1886-1959). Tolman, for example, wrote that "everything important in psychology . . . can be investigated in essence through the continued experimental and theoretical analysis of the determiners of rat behavior at a choice point in a maze" (1938, p. 34).

Behaviorists created journals, organized societies, and founded psychology graduate programs reflective of behaviorism. Behaviorists organized themselves into different types of research clusters, whose differences stemmed from such factors as varying approaches to conditioning and experimentation. Some clusters were named as follows: "the experimental analysis of behavior", "behavior analysis", "functional analysis", and, of course, "radical behaviorism". These labels sometimes were responsible for the titles of behaviorism's leading societies and journals, including the Society for the Advancement of Behavior Analysis (SABA), and the Journal of the Experimental Analysis of Behavior (begun in 1958) as well as the Journal of Applied Behavior Analysis (begun in 1968).

Behaviorism generated a type of therapy, known as behavior therapy (see Rimm and Masters 1974; Erwin 1978). It developed behavior management techniques for autistic children (see Lovaas and Newsom 1976) and token economies for the management of chronic schizophrenics (see Stahl and Leitenberg 1976). It fueled discussions of how best to understand the behavior of nonhuman animals, the relevance of laboratory study to the natural environmental occurrence of behavior, and whether there is built-in associative bias in learning (see Schwartz and Lacey 1982).

Behaviorism stumbled upon various critical difficulties with its commitments. One difficulty is confusion about the effects of reinforcement (see Gallistel 1990). In its original sense, a stimulus is a reinforcer only if its presentation increases the frequency of a response in a type of associative conditioning known as operant conditioning. A problem with this definition is that it defines reinforcers as stimuli that change behavior. The presentation of food, however, may have no observable effect on response frequency. It may, instead, be associated with an animal's ability to identify and remember temporal or spatial properties of the circumstances in which reinforcement occurs. This and other difficulties prompted changes in behaviorism's commitments and new directions of research. One recent and fresh direction has been the study of the role of short term memory in contributing to reinforcement effects on the so-called trajectory of behavior (see Killeen 1994).

Another stumbling block, in the case of analytical behaviorism, is the fact that the behavioral sentences that are intended to offer the behavioral paraphrases of mental terms almost always use mental terms themselves (see Chisholm 1957). In the example of my belief that I have a 2pm dental appointment, one

must also speak of my desire to arrive at 2pm, otherwise the behavior of arriving at 2pm could not count as believing that I have a 2pm appointment. The term "desire" is a mental term. Critics have charged that we can never escape from using mental terms in the characterization of the meaning of mental terms. This suggests that mental discourse cannot be displaced by behavioral discourse. At least it cannot be displaced term-by-term. Perhaps analytical behaviorists need to paraphrase a whole swarm of mental terms at once (see Rey 1997, p. 154-5).

Why be a Behaviorist

Why would anyone be a behaviorist? There are three main reasons (see also Zuriff 1985).

The first is epistemic. Warrant or evidence for saying that an animal or person is in a certain mental state, for example, possesses a certain belief, is grounded in behavior, understood as observable behavior. Moreover, the conceptual space between the claim that behavior warrants the attribution of belief and the claim that believing consists in behavior is a short and in some ways appealing step. If we look, for example, at how people are taught to use mental concepts and terms -- terms like "believe", "desire", and so on -- the conditions of use appear inseparably connected with behavioral tendencies in certain circumstances.

The second reason can be expressed as follows: One major difference between mentalistic (mental states in-the-head) and associationist or conditioning accounts of behavior is that mentalistic accounts tend to have a strong nativist bent. This is true even though there may be nothing inherently nativist about mentalistic accounts (see Cowie 1998).

Mentalistic accounts tend to assume, and sometimes even explicitly to embrace (see Fodor 1981), the hypothesis that the mind possesses at birth or innately a set of procedures or internally represented processing rules which are deployed when learning or acquiring new responses. Behaviorism, by contrast, is anti-nativist. Behaviorism, therefore, appeals to theorists who deny that there are innate rules by which organisms learn. To Skinner and Watson organisms learn without being innately or pre-experientially provided with explicit procedures by which to learn. Learning does not consist in rule-governed behavior. Learning is what organisms do in response to stimuli. A behaviorist organism learns, as it were, from its successes and mistakes. (See Dennett 1978).

Much contemporary work in cognitive science on the set of models known as connectionist or parallel distributed processing (PDP) models seems to share behaviorism's anti-nativism about learning. PDP takes an approach to learning which is response oriented rather than rule-governed and this is because, like behaviorism, it has roots in associationism (see Bechtel 1985; compare Graham 1991 with Maloney 1991). Whether PDP models ultimately are or must be anti-nativist depends upon what counts as native or innate rules (Bechtel and Abrahamsen 1991, pp. 103-105).

The third reason for behaviorism's appeal, popular at least historically, is related to its disdain for

reference to inner mental or information processing as a means to explain behavior. The disdain is most vigorously exemplified in the work of Skinner. Skinner's skepticism about explanatory references to mental innerness may be expressed as follows.

Behavior must be explained in terms which do not themselves presuppose the very thing that is explained. This is behavior. The outside (public) behavior of a person is not accounted for by referring to the inside (inner processing) behavior of the person (say, his or her internal problem solving or thinking) if, therein, the behavior of the person is unexplained. "The objection," wrote Skinner, "to inner states is not that they do not exist, but that they are not relevant in a functional analysis" (Skinner 1953, p. 35). ‘Not relevant’ means, for Skinner, explanatorily circular or regressive.

Skinner charges that since mental activity is a form of behavior (albeit inner), the only non-regressive, non-circular way to explain behavior is to appeal to something non-behavioral. This non-behavioral something is environmental stimuli and an organism's interactions with, and reinforcement from, the environment.

So, the third reason for behaviorism's appeal is that it tries to avoid circular, regressive explanations of behavior. It aims to refrain from accounting for one type of behavior (overt) in terms of another type of behavior (covert), all the while, in some sense, leaving behavior unexplained.

It should be noted that Skinner's views about explanation are particularly extreme (scientifically naive?), and that many who called themselves behaviorists including Guthrie, Tolman, and Hull, or continue to work within the tradition, broadly understood, including Killeen (1987) and Rescorla (1990), take exception to much that Skinner has said about explanatory references to innerness. It should also be noted that Skinner's derisive attitude towards explanatory references to mental innerness stems, in part, from his conviction that if the language of psychology is permitted to refer to internal processing in its explanations of behavior, this goes some way towards permitting talk of immaterial mental substances, agents endowed with contra-causal free will, and little persons (homunculi) within bodies, each of which Skinner takes to be incompatible with a scientific worldview (see Skinner 1971). Finally, it must be emphasized that Skinner's aversion to explanatory references to innerness is not an aversion to inner states or processes per se. Skinner countenances talk of inner events provided that they are treated in the same manner as public responses. "An adequate science of behavior," he wrote, "must consider events taking place within the skin of the organism . . . as part of behavior itself" (1984, p. 617).

This last point is worth additional discussion, since the failure to appreciate Skinner's willingness to talk of inner events has helped to produce confusion in understanding his attitude towards the mental. Skinner does not deny the existence of events such as thinking and perceiving or various other events which he sometimes classifies as mental or inner. True, it is hard to know what Skinner counts as inner, or mental, and why, especially given that he sometimes uses terms like ‘inner’ and ‘mental’ as epithets of dismissal. However, set against Skinner's derision of the mental is his persistent reminder that people think, perceive and therein respond beneath their skin. So, Skinner pictures inner events as follows.

Inner events are those about which we may make introspective reports (and thus they are private, observationally), but their causal explanatory force is idle. Because inner events are private observationally, their patterns of reinforcement are more elusive, less easy to deliberately regulate, than overt behavior. However, inner events are responses, ultimately, to environmental stimuli.

Skinner's Social Worldview

Skinner is the only major figure in the history of behaviorism to offer a socio-political world view based on his commitment to behaviorism. Skinner constructed a theory as well as narrative picture in Walden Two (1948) of what an ideal human society would be like if designed according to behaviorist principles (see also Skinner 1971). Skinner's social worldview illustrates both his aversion to free will, to homunculi, to dualism as well as his reasons for claiming that a person's history of environmental interactions controls his or her behavior.

One remarkable feature of human behavior which Skinner deliberately rejects is that people creatively make their own environments (see Chomsky 1971, Black 1973). The world is as it is, in part, because we make it that way. Skinner protests that "it is in the nature of an experimental analysis of human behavior that it should strip away the functions previously assigned to autonomous man and transfer them one by one to the controlling environment" (1971, p. 198).

Critics have raised several objections to the Skinnerian social picture. One of the most persuasive, and certainly one of the most frequent, adverts to Skinner's vision of the ideal human society. It is a question asked of the fictional founder of Walden Two, Frazier, by the philosopher Castle. It is the question of what is the best social mode of existence for a human being. Frazier's, and therein Skinner's, response to this question is both too general and incomplete. Frazier/Skinner speaks of the values of health, friendship, relaxation, rest, and so forth. However, these values are hardly the detailed basis of a social system.

There is a notorious problem in social theory of specifying the appropriate level of detail at which a blueprint for a new and ideal society must be presented (see Arnold 1990, pp. 4-10). Skinner identifies the behavioristic principles and learning incentives that he hopes will reduce systematic injustices in social systems. He also describes a few practices (concerning child rearing and the like) that are intended to contribute to human happiness. However he offers only the haziest descriptions of the daily lives of Walden Two citizens and no suggestions for how best to resolve disputes about alternative ways of life that are prima facie consistent with behaviorist principles (see Kane 1996, p. 203). He gives little or no serious attention to the crucial general problem of inter-personal conflict resolution and to the role of institutional arrangements in resolving conflicts.

In an essay which appeared in The Behavior Analyst (1985), nearly forty years after the publication of Walden Two, Skinner, in the guise of Frazier, tried to clarify his characterization of ideal human circumstances. He wrote that in the ideal human society "people just naturally do the things they need to do to maintain themselves . . . and treat each other well, and they just naturally do a hundred other things

they enjoy doing because they do not have to do them" (p. 9). However, of course, doing a hundred things humans enjoy doing means only that Walden Two is vaguely defined, not that its culturally instituted habits and the character of its institutions merit emulation.

The incompleteness of Skinner's description of the ideal human society or life is so widely acknowledged that one might wonder if actual experiments in Walden Two living could lend useful detail to his blueprint. At least two such experiments have been and are being conducted, one in Virginia, the other in Mexico. Both can be indirectly explored via the Internet (see Other Internet Resources).

Why be Anti-Behaviorist

Behaviorism is unpopular. It is dismissed by cognitive scientists developing intricate internal information processing models. It is neglected by cognitive ethologists and ecological psychologists convinced that its methods are irrelevant to studying how animals and persons behave in their natural and social environment. It is rejected by neuroscientists sure that direct study of the brain is the only way to understand the causes of behavior.

Remnants of behaviorism survive in both behavior therapy and laboratory-based animal learning theory. In the metaphysics of mind, too, behavioristic themes survive in the approach to mind known as functionalism. Functionalism defines states of mind as states that play particular causal-functional roles in animals or systems in which they occur. Paul Churchland writes of functionalism as follows: "The essential or defining feature of any type of mental states is the set of causal relations it bears to . . . bodily behavior (1984, p. 36). This functionalist notion is similiar to the behaviorist idea that reference to behavior and to stimulus/response relations enters centrally and essentially into any account of what it means for a creature to behave or to be subject, in the scheme of analytical behaviorism, to the attribution of mental states.

Remnants, however, are remnants. Behaviorism has lost strength and influence. Why?

The deepest and most complex reason for behaviorism's demise is its commitment to the thesis that behavior can be explained without reference to mental activity. Many philosophers and psychologists find this thesis hopelessly restrictive. They reject behaviorism because of it. At the lunch table, for instance, I recognize a situation in which I am presented with apples as a situation in which I am presented with apples and I form concepts of apples, sort apples into classes (e.g. ripe and unripe), and draw upon those classifications as the situation permits, eating a ripe apple and avoiding unripe apples. Recognizing, conceptually sorting, and drawing upon are information processing activities which take place inside my head -- in my mind. These events are not (overt) behavior, although they may be revealed or expressed in behavior and reference to them helps to explain behavior.

To illustrate the explanatory counter-intuitiveness of restricting psychology to outside-the-head environmental histories, suppose that one morning Mother Nature throws a lightening bolt at a swamp

and that, in the consequent chemical reaction, a creature appears in the swamp that is a molecule-for-molecule duplicate of some actual human being -- me, say. Should Swamp Me step out of the swamp, as I would step out of the swamp?

Since Swamp Me is an exact physical duplicate of me, whatever physical stimulus is applied, we may think, he should react to the stimulus in the same manner that I would, and produce exactly the same response. We should picture him as possessing my behavioral tendencies before his first behavioral response. Is this picture compatible with behaviorism?

At the very least, the expectation that Swamp Me behaves just as I would is prima facie incompatible with behaviorism. This is because Swamp Me has no environmental history. He has not been reinforced for anything.

Alternatively, one might reply that Swamp Me shares in my behavioral tendencies by virtue of being my physical duplicate. For an organism to have a behavioral disposition, it shouldn't be necessary for the organism to have its own learning history. What is at least equally sufficient is what is encoded or stored in its head. It must have a record of a learning history embedded in its brain or central nervous system. One need not insist that this is the organism's own history. Swamp Me may act just as I would act, however this is only because it ‘remembers’ certain behaviors and reinforcement for those behaviors.

This sort of reply seems pretty obvious. However, one might wonder whether it is compatible with behaviorism. Here's why.

The memory-in-the-head model of Swamp Me seems not be a behaviorist theory, as behaviorists have expressed their theories. Instead, it is close to a non-behaviorist account of the significance of having a reinforcement history, where what matters is the internal record, and not what occurs in the world (the history).

The critical question is what counts as a record of a reinforcement history. Many psychologists despair of describing what counts as a record without postulating internal memory states and internal processing over those states (see Roediger and Goff 1998). Because memory states serve to record past experiences and reinforcements, and serve referentially to stand for stimulus conditions which the organism remembers, they are commonly described as internal mental representations. Talk of internal mental representation, however, is a perspective from which behaviorism -- at least of Skinner and other traditional behaviorists -- has wished to depart.

One defining feature of traditional behaviorism is that it tried to free psychology from having to theorize about how animals and persons represent their environment. This was important, historically, because it seemed that behavior/environment connections are a lot clearer and more manageable experimentally than internal representations. Unfortunately, for behaviorism, it's hard to imagine a more restrictive rule for psychology than a rule which prohibits hypotheses about representational storage and processing. Stich, for example, complains against Skinner that "we now have an enormous collection of experimental

data which, it would seem, simply cannot be made sense of unless we postulate something like" information processing mechanisms in the heads of organisms (1998, p. 649).

A second reason for rejecting behaviorism is that some features of mentality -- some elements in the inner processing of persons -- have characteristic ‘feels’ or sensory or phenomenal qualities. To be in pain, for example, is not merely to produce appropriate pain behavior under the right environmental circumstances, it is to experience a ‘like-thisness’ to the pain (as something dull or sharp, perhaps). Behaviorist creatures may engage in pain behavior, including beneath the skin pain responses, yet completely lack whatever is qualitatively definitive of pain (its feel). (See also Graham 1998, pp. 47-51.; Graham and Horgan 2000).

Feels, or qualia, as they also are called, are difficult for behaviorism because feels subjectively are present in experience, but resist behavioral analysis or description. Indeed, it is tempting to postulate that feels affect non-qualitative elements of internal processing, and that they, for example, contribute to arousal, attention, and receptivity to associative conditioning.

The third reason for rejecting behaviorism is connected with Noam Chomsky. Chomsky has been one of behaviorism's most successful and damaging critics. In a review of Skinner's book on verbal behavior (see above), Chomsky (1959) argued that some behavior (linguistic behavior, in particular) has to be understood in terms of internally represented rules. These rules are not products of learned associations. They are part of our native psychological endowment as human beings. Chomsky charged that behaviorist models of language learning cannot explain various facts about language acquisition, such as the rapid acquisition of language by young children, which is sometimes referred to as the phenomenon of "lexical explosion". A child's linguistic abilities appear to be radically under-determined by the evidence of verbal behavior offered to the child in the short period in which he or she acquires those abilities. By the age of four or five (normal) children have an almost limitless capacity to understand and produce sentences which they have never heard before. The basic rules or principles of grammar, therefore, argues Chomsky, must be innate.

The problem to which Chomsky refers, which is the problem of behavioral capacities outstripping individual learning histories, seems to go beyond merely the issue of linguistic behavior in young children. It appears to be a fundamental fact about human beings that our sensitivities and behavioral capacities often surpass the limitations of our individual learning histories. Our history of reinforcement often is too impoverished to determine uniquely our behavior. Much learning, therefore, seems to require pre-existing or innate representational structures within which learning occurs. (See also Brewer 1974, but compare with Bates et al. 1998 and Cowie 1998).

Conclusion

In 1977 Willard Day, a behavioral psychologist and founding editor of the journal Behaviorism, published Skinner's "Why I am not a cognitive psychologist" (Skinner 1977). Skinner began the paper by stating that "the variables of which human behavior is a function lie in the environment" (p. 1). Skinner

ended by remarking that "cognitive constructs give . . . a misleading account of what" is inside a human being (p. 10)

More than a decade earlier, in 1966 Hempel announced his defection from behaviorism:

> In order to characterize . . . behavioral patterns, propensities, or capacities . . . we need not only a suitable behavioristic vocabulary, but psychological terms as well. (p. 110)

Hempel had come to believe that it is a mistake to imagine that human behavior can be understood exclusively in non-mental, behavioristic terms.

Contemporary philosophy and psychology largely share Hempel's conviction that the explanation of behavior cannot omit invoking a creature's representation of its world. Psychology must use psychological terms. Behavior without representation is blind. Psychological theorizing without reference to internal processing is explanatorily impaired. Behaviorism, not cognitive science or psychology, offers a misleading account of what is inside the head.

Qualia

Feelings and experiences vary widely. For example, I run my fingers over sandpaper, smell a skunk, feel a sharp pain in my finger, seem to see bright purple, become extremely angry. In each of these cases, I am the subject of a mental state with a very distinctive subjective character. There is something it is *like* for me to undergo each state, some phenomenology that it has. Philosophers often use the term ‘qualia’ (singular ‘quale’) to refer to the introspectively accessible, phenomenal aspects of our mental lives. In this standard, broad sense of the term, it is difficult to deny that there are qualia. Disagreement typically centers on which mental states have qualia, whether qualia are intrinsic qualities of their bearers, and how qualia relate to the physical world both inside and outside the head. The status of qualia is hotly debated in philosophy largely because it is central to a proper understanding of the nature of consciousness. Qualia are at the very heart of the mind-body problem.

The entry that follows is divided into eight sections. The first comments on other more restricted uses of the term ‘qualia’. The second addresses the question of which mental states have qualia. The third section brings out some of the main arguments for the view that qualia are irreducible and non-physical. The remaining sections focus on functionalism and qualia, the explanatory gap, qualia and introspection, representational theories of qualia, and finally the issue of qualia and simple minds.

I. Other Uses of the Term ‘Qualia’

Consider a painting of a dalmatian. Viewers of the painting can apprehend not only its content (i.e., its representing a dalmatian) but also the colors, shapes, and spatial relations obtaining among blobs of paint partly by virtue of which it has that content. It has sometimes been supposed that being aware or conscious of a visual experience is like viewing an inner, non-physical picture or sense-datum. So, for example, on this conception, if I see a dalmatian, I am subject to a mental picture-like representation of a dalmatian (a sense-datum), introspection of which reveals to me both its content and its intrinsic, non-intentional features partly by virtue of which it has that content. These intrinsic, non-intentional features have been taken by advocates of the sense-datum theory to be the sole determinants of what it is like for me to have the experience. In a second, more restricted sense of the term ‘qualia’, then, qualia are intrinsic, consciously accessible, non-intentional features of sense-data and other non-physical phenomenal objects that are responsible for their phenomenal character.

With the demise of the sense-datum theory, there are very few philosophers who believe that there are qualia, so conceived. Still, there is another established sense of the term ‘qualia’, which is similar to the one just given but which does not demand of qualia advocates that they endorse the now discredited sense-datum theory. However sensory experiences are ultimately analyzed -- whether, for example, they are taken to involve relations to sensory objects or they are identified with neural events or they are held to be physically irreducible events -- many philosophers suppose that they have intrinsic, consciously accessible features that are neither intentional nor intentionally determined and that are solely responsible for their phenomenal character. These features, whatever their ultimate nature, physical or non-physical, are often dubbed ‘qualia’.

In the case of visual experiences, for example, it is frequently supposed that there is a range of visual qualia, where these are taken to be intrinsic features that (a) are accessible to introspection, (b) can vary without any variation in the intentional contents of the experiences, (c) are mental counterparts to some directly visible properties of objects (e.g., color), and (d) are the sole determinants of the phenomenal character of the experiences. Philosophers who hold or have held this view include, for example, Nagel (1974), Peacocke (1983) and Block (1990).

Philosophers who deny that there are qualia often have in mind qualia, as the term is used in the senses specified in this section. Sometimes their target is qualia, conceived of as in the opening paragraph of the entry, but with the additional assumption (often not explicitly stated) that qualia are ineffable or nonphysical or ‘given’ to their subjects incorrigibly (without the possibility of error). Thus, announcements by philosophers who declare themselves opposed to qualia (e.g., Dennett 1987, 1991) need to be treated with some caution. One can agree that there are no qualia in the more restricted senses I have explained, and also agree that there are no ineffable or incorrigibly presented or non-physical qualities possessed by our mental states, while still endorsing qualia, in the standard broad sense.

In the rest of this entry, I shall use the term ‘qualia’ in the standard, broad way I did at the beginning of the entry. So, I shall take it for granted that there are qualia.

II. Which Mental States Possess Qualia?

The following would certainly be included on my own list. (1) Perceptual experiences, for example, experiences of the sort involved in seeing green, hearing loud trumpets, tasting liquorice, smelling the sea air, handling a piece of fur. (2) Bodily sensations, for example, feeling a twinge of pain, feeling an itch, feeling hungry, having a stomach ache, feeling hot, feeling dizzy. Think here also of experiences such as those present during orgasm or while running flat-out. (3) Felt reactions or passions or emotions, for example, feeling delight, lust, fear, love, feeling grief, jealousy, regret. (4) Felt moods, for example, feeling elated, depressed, calm, bored, tense, miserable. (For more here, see Haugeland 1985, pp. 230-235).

Should we include any other mental states on the list? Galen Strawson has recently claimed (1994) that there are such things as the *experience* of understanding a sentence, the *experience* of suddenly thinking of something, of suddenly remembering something, and so on. Moreover, in his view, experiences of these sorts are not reducible to associated sensory experiences and/or images. Strawson's position here seems to be that thought-experience is a distinctive experience in its own right. He says, for example: "Each sensory modality is an experiential modality, and thought experience (in which understanding-experience may be included) is an experiential modality to be reckoned alongside the other experiential modalities" (p. 196). On Strawson's view, then, some thoughts have qualia.

This view is controversial. One response is to claim that the phenomenal aspects of understanding derive largely from linguistic (or verbal) images, which have the phonological and syntactic structure of items in the subject's native language. These images frequently even come complete with details of stress and intonation. As we read, it is sometimes phenomenally as if we are speaking to ourselves. (Likewise when we consciously think about something without reading). We often "hear" an inner voice. Depending upon the content of the passage, we may also undergo a variety of emotions and feelings. We may feel tense, bored, excited, uneasy, angry. Once *all* these reactions are removed, together with the images of an inner voice and the visual sensations produced by reading, some would say (myself included) that no phenomenology remains.

In any event, images and sensations of the above sorts are not always present in thought. They are not *essential* to thought. Consider, for example, the thoughts involved in everyday visual recognition (or the thoughts of creatures without a natural language). Consider also deeply unconscious thoughts. So, certainly some thoughts lack qualia.

What about desires, for example, my desire for a week's holiday in Venice? It is certainly true that in some cases, there is an associated phenomenal character. Often when we strongly desire something, we experience a feeling of being "pulled" or "tugged". There may also be accompanying images in various modalities.

Should we include such propositional attitudes as feeling angry *that the house has been burgled* or seeing *that the computer is missing* on the list? These seem best treated as hybrid or complex states, one component of which is essentially a phenomenal state and the other (a judgment or belief) is not. Thus, in

both cases, there is a constituent experience that is the real bearer of the relevant quale or qualia.

III. Are Qualia Irreducible, Non-Physical Entities?

The literature on qualia is filled with thought-experiments of one sort or another. Perhaps the most famous of these is the case of Mary, the brilliant color scientist. Mary, so the story goes (Jackson 1982), is imprisoned in a black and white room. Never having been permitted to leave it, she acquires information about the world outside from the black and white books her captors have made available to her, from the black and white television sets attached to external cameras, and from the black and white monitor screens hooked up to banks of computers. As time passes, Mary acquires more and more information about the physical aspects of color and color vision. (For a real life case of a visual scientist (Knut Nordby) who is an achromotope, see Sacks 1996, Chapter 1.) Eventually, Mary becomes the world's leading authority on these matters. Indeed she comes to know *all* the physical facts pertinent to everyday colors and color vision.

Still, she wonders to herself: What do people in the outside world *experience* when they see the various colors? What is it *like* for them to see red or green? One day her captors release her. She is free at last to see things with their real colors (and free too to scrub off the awful black and white paint that covers her body). She steps outside her room into a garden full of flowers. "So, that is what it is like to experience red," she exclaims, as she sees a red rose. "And that," she adds, looking down at the grass, "is what it is like to experience green."

Mary here seems to make some important discoveries. She seems to find out things she did not know before. How can that be, if, as seems possible, at least in principle, she has all the physical information there is to have about color and color vision -- if she knows all the pertinent physical facts?

One popular explanation among philosophers (so-called ‘qualia freaks’) is that that there is a realm of subjective, phenomenal qualities associated with color, qualities the intrinsic nature of which Mary comes to discover upon her release, as she herself undergoes the various new color experiences. Before she left her room, she only knew the objective, physical basis of those subjective qualities, their causes and effects, and various relations of similarity and difference. She had no knowledge of the subjective qualities in themselves.

This explanation is not available to the physicalist. If what it is like for someone to experience red is one and the same as some physical quality, then Mary already knows *that* while in her room. Likewise, for experiences of the other colors. For Mary knows all the pertinent physical facts. What, then, can the physicalist say?

Some physicalists respond that knowing what it is like is know-how and nothing more. Mary acquires certain abilities, specifically in the case of red, the ability to recognize red things by sight alone, the ability to imagine a red expanse, the ability to remember the experience of red. She does *not* come to know any new information, any new facts about color, any new qualities. This is the view of David Lewis

(1990) and Lawrence Nemirow (1990).

The Ability Hypothesis, as it is often called, is more resilient than many philosophers suppose (see Tye forthcoming (a)). But it has difficulty in properly accounting for our knowledge of what it is like to undergo experiences of determinate hues while we are undergoing them. For example, I can know what it is like to experience red-17, as I stare at a rose of that color. Of course, I don't know the hue as red-17. My conception of it is likely just *that shade of red*. But I certainly know what it is like to experience the hue while it is present. Unfortunately, I lack the abilities Lewis cites and so does Mary even after she leaves her cell. She is not able to recognize things that are red-17 as red-17 by sight. Given the way human memory works and the limitations on it, she lacks the concept red-17. She has no mental template that is sufficiently fine-grained to permit her to identify the experience of red-17 when it comes again. Presented with two items, one red-17 and the other red-18, in a series of tests, she cannot say with any accuracy which experience her earlier experience of the rose matches. Sometimes she picks one; at other times she picks the other. Nor is she able afterwards to imagine things as having hue, red-17, or as having that very shade of red the rose had; and for precisely the same reason.

The Ability Hypothesis appears to be in trouble. An alternative physicalist proposal is that Mary in her room lacks certain *phenomenal concepts*, certain ways of thinking about or mentally representing color experiences and colors. Once she leaves the room, she acquires these new modes of thought as she experiences the various colors. Even so, the qualities the new concepts pick out are ones she knew in a different way in her room, for they are physical or functional qualities like all others.

One problem this approach faces is that it seems to imply that Mary does not really make a new discovery when she says, "So, that is what it is like to experience red." Upon reflection, however, it is far from obvious that this is really a consequence. For it is widely accepted that concepts or modes of presentation are involved in the individuation of thought-contents, given one sense of the term ‘content’ -- the sense in which thought-content is whatever information that-clauses provide that suffices for the purposes of even the most demanding rationalizing explanation. In this sense, what I think, when I think that Cicero was an orator, is not what I think when I think that Tully was an orator. This is precisely why it is possible to discover that Cicero is Tully. The thought that Cicero was an orator differs from the thought that Tully was an orator not at the level of truth-conditions -- the same singular proposition is partly constitutive of the content of both -- but at the level of concepts or mode of presentation. The one thought exercises the concept *Cicero*; the other the concept *Tully*. The concepts have the same reference, but they present the referent in different ways and thus the two thoughts can play different roles in rationalizing explanation.

So, there is no real difficulty in holding both that Mary comes to know some new things upon her release, while already knowing all the pertinent real-world physical facts, even though the new experiences she undergoes and their introspectible qualities are wholly physical. In an ordinary, everyday sense, Mary's knowledge increases. And that is all the physicalist needs to answer the Knowledge Argument. (The term ‘fact’, I should add, is itself ambiguous. Sometimes it is used to pick out real-world states of affairs alone; sometimes it is used for such states of affairs under certain conceptualizations. When I speak of the physical facts above, I should be taken to refer either to physical states of affairs alone or to those states of affairs under purely physical conceptualizations. For more on ‘fact’, see Tye 1995.)

Some philosophers insist that the difference between the old and the new concepts in this case is such that there must be a difference in the world between the properties these concepts stand for or denote (Jackson 1993, Chalmers 1996). Some of these properties Mary knew in her cell; others she becomes cognizant of only upon her release. The physicalist is committed to denying this claim.

The issues here are complex. If a necessary a posteriori identity claim about properties requires for its truth that one or the other of the rigid terms flanking the identity sign be a priori connected to a different property from the one it denotes (so that the mode of presentation is wholly distinct from the referent) then it may seem that physicalism about qualia is in trouble. For phenomenal terms are often viewed as picking out phenomenal qualities via those very qualities. (This point, or one very like it, is sometimes put within the framework of two-dimensional modal semantics by saying that phenomenal terms have the same primary and secondary intensions). But even granting this claim, the above view of necessary a posteriori identities entails that physicalism about qualia is false only if it is true that the physical term on the right hand side of the identity sign itself refers via a mode of presentation that is the same as the referent (so that its primary intension is the same as its secondary one). And, in general, that cannot be correct. To see this, consider a purely theoretical identity, that between H_2O and a certain quantum-mechanical system. The identity claim here is necessary a posteriori, assuming that 'H_2O' and the appropriate quantum-mechanical designator are both rigid. So, if a condition of a property identity being necessary a posteriori is that one or other of the designators express a concept whose mode of presentation is different from its referent, then we have, with this example, a case where the mode of presentation and the referent come apart for at least one of the theoretical terms (and arguably for both). Why not, then, for the rigid physical designator in the case of a phenomenal-physical identity?

Another famous anti-reductionist thought-experiment concerning qualia appeals to the possibility of zombies. A philosophical zombie is a molecule by molecule duplicate of a sentient creature, a normal human-being, for example, but who differs from that creature in lacking *any* phenomenal consciousness. For me, as I lie on the beach, happily drinking some wine and watching the waves, I undergo a variety of visual, olfactory, and gustatory experiences. But my zombie twin experiences nothing at all. He has no phenomenal consciousness. Since my twin is an exact physical duplicate of me, his inner psychological states will be *functionally* isomorphic with my own (assuming he is located in an identical environment). Whatever physical stimulus is applied, he will process the stimulus in the same way as I do, and produce exactly the same behavioral responses. Indeed, on the assumption that non-phenomenal psychological states are functional states (that is, states definable in terms of their role or function in mediating between stimuli and behavior), my zombie twin has just the same beliefs, thoughts, and desires as I do. He differs from me only with respect to experience. For him, there is nothing it is like to stare at the waves or to sip wine.

The hypothesis that there can be philosophical zombies is not normally the hypothesis that such zombies are *nomically* possible, that their existence is consistent with the actual laws of nature. Rather the suggestion is that zombie replicas of this sort are at least *imaginable* and hence metaphysically possible.

Philosophical zombies pose a serious threat to any sort of physicalist view of qualia. To begin with, if zombie replicas are metaphysically possible, then there is a simple argument that seems to show that phenomenal states are not identical with internal, objective, physical states. Suppose objective, physical state *P* can occur without phenomenal state *S* in some appropriate zombie replica (in the metaphysical sense of 'can' noted above). Intuitively *S* cannot occur without *S*. Pain, for example, cannot be felt without pain. So, *P* has a modal property *S* lacks, namely the property of *possibly* occurring without *S*. So, by Leibniz' Law (the law that for anything *x* and for anything *y*, if *x* is identical with *y* then *x* and *y* share *all* the same properties), *S* is not identical with *P*.

Secondly, if a person microphysically identical with me, located in an identical environment (both present and past), can lack *any* phenomenal experiences, then facts pertaining to experience and feeling, facts about qualia, are not necessarily fixed or determined by the objective microphysical facts. And this the physicalist cannot allow, even if she concedes that phenomenally conscious states are not strictly identical with internal, objective, physical states. For the physicalist, whatever her stripe, must at least believe that the microphysical facts determine all the facts, that any world that was exactly like ours in *all* microphysical respects (down to the smallest detail, to the position of every single boson, for example) would have to be like our world in all respects (having identical mountains, lakes, glaciers, trees, rocks, sentient creatures, cities, and so on).

One well-known physicalist reply to the case of zombies (Loar 1990) is to grant that they are conceptually possible, or at least that there is no *obvious* contradiction in the idea of a zombie, while denying that zombies are metaphysically possible. Since the anti-physicalist argument requires metaphysical possibility -- mere conceptual possibility will not suffice -- it now collapses. That conceptual possibility is too weak for the anti-physicalist's purposes (at least without further qualification and argument) is shown by the fact that it is conceptually possible that I am not Michael Tye (that I am an impostor or someone misinformed about his past) even though, given the actual facts, it is metaphysically impossible.

IV. Functionalism and Qualia

Functionalism is the view that individual qualia have functional natures, that the phenomenal character of, e.g., pain is one and the same as the property of playing such-and-such a causal or teleofunctional role in mediating between physical inputs (e.g., body damage) and physical outputs (e.g., withdrawal behavior). On this view (Lycan 1987), qualia are multiply physically realizable. Inner states that are physically very different may nonetheless feel the same. What is crucial to what it is like is functional role, not underlying hardware.

There are two famous objections to functionalist theories of qualia: the Inverted Spectrum and the Absent Qualia Hypothesis. The first move in the former objection consists in claiming that you might see red when I see green and vice-versa; likewise for the other colors so that our color experiences are phenomenally inverted. This does not suffice to create trouble for the functionalist yet. For you and I are surely representationally different here: for example, you have a visual experience that represents red

when I have one that represents green. And that representational difference brings with it a difference in our patterns of causal interactions with external things (and thereby a functional difference).

This reply can be handled by the advocate of inverted qualia by switching to a case in which we both have visual experiences with the same representational contents on the same occasions while still differing phenomenally. Whether such cases are really metaphysically possible is open to dispute, however. Certainly, those philosophers who are representationalists about qualia (see Section VII) would deny their possibility. Indeed, it is not even clear that such cases are conceptually possible (Harrison 1973, Hardin 1993, Tye 1995). But leaving this to one side, it is far from obvious that there would not have to be some salient fine-grained functional differences between us, notwithstanding our gross functional identity.

Consider a computational example. For any two numerical inputs, *M* and *N*, a given computer always produces as outputs the product of *M* and *N*. There is a second computer that does exactly the same thing. In this way, they are functionally identical. Does it follow that they are running exactly the same program? Of course, not! There are all sorts of programs that will multiply together two numbers. These programs can differ dramatically. At one gross level the machines are functionally identical, but at lower levels the machines can be functionally different.

In the case of you and me, then, the opponent of inverted qualia can claim that, even if we are functionally identical at a coarse level - we both call red things ‘red’, we both believe that those things are red on the basis of our experiences, we both are caused to undergo such experiences by viewing red things, etc. - there are necessarily fine-grained differences in our internal functional organization. And that is why our experiences are phenomenally different.

Some philosophers will no doubt respond that it is still imaginable that you and I are functionally identical in *all* relevant respects yet phenomenally different. But this claim presents a problem at least for those philosophers who oppose functionalism but who accept physicalism. For it is just as easy to imagine that there are inverted qualia in molecule-by-molecule duplicates (in the same external, physical settings) as it is to imagine inverted qualia in functional duplicates. If the former duplicates are really metaphysically impossible, as the physicalist is committed to claiming, why not the latter? Some further convincing argument needs to be given that the two cases are disanalogous. As yet, to my mind, no such argument has been presented. (Of course, this response does not apply to those philosophers who take the view that qualia are irreducible, non-physical entities. However, these philosophers have other severe problems of their own. In particular, they face the problem of phenomenal causation. Given the causal closure of the physical, how can qualia make any difference? For more here, see Tye 1995, Chalmers 1996).

The absent qualia hypothesis is the hypothesis that functional duplicates of sentient creatures are possible, duplicates that entirely lack qualia. For example, one writer (Block (1980)) asks us to suppose that a billion Chinese people are each given a two-way radio with which to communicate with one another and with an artificial (brainless) body. The movements of the body are controlled by the radio signals, and the signals themselves are made in accordance with instructions the Chinese people receive from a vast

display in the sky which is visible to all of them. The instructions are such that the participating Chinese people function like individual neurons, and the radio links like synapses, so that together the Chinese people duplicate the causal organization of a human brain. Whether or not this system, if it were ever actualized, would *actually* undergo any feelings and experiences, it seems coherent to suppose that it might not. But if this is a real metaphysical possibility, then qualia do not have functional essences.

One standard functionalist reply to cases like the China-body system is to bite the bullet and to argue that however strange it seems, the China-body system could not fail to undergo qualia. The oddness of this view derives, according to some functionalists (Lycan 1987), from our relative size. We are each so much smaller than the China-body system that we fail to see the forest for the trees. Just as a creature the size of a neuron trapped inside a human head might well be wrongly convinced that there could not be consciousness there, so we too draw the wrong conclusion as we contemplate the China-body system. It has also been argued (e.g., by Shoemaker 1975) that any system that was a full functional duplicate of one of us would have to be subject to all the same beliefs, including beliefs about its own internal states. Thus the China-Body system would have to believe that it experiences pain; and if it had beliefs of this sort, then it could not fail to be the subject of some experiences (and hence some states with phenomenal character). If this reply is successful, what it shows is that the property of having some phenomenal character or other has a functional essence. But it does not show that individual qualia are functional in nature. Thus one could accept that absent qualia are impossible while also holding that inverted spectra are possible (see, e.g., Shoemaker 1975).

V. Qualia and the Explanatory Gap

Our grasp of what it is like to undergo phenomenal states is supplied to us by introspection. We also have an admittedly incomplete grasp of what goes on objectively in the brain and the body. But there is, it seems, a vast chasm between the two. It is very hard to see how this chasm in our understanding could ever be bridged. For no matter how deeply we probe into the physical structure of neurons and the chemical transactions which occur when they fire, no matter how much objective information we come to acquire, we still seem to be left with something that we cannot explain, namely, why and how such-and-such objective, physical changes, whatever they might be, generate so-and-so subjective feeling, or any subjective feeling at all.

This is the famous "explanatory gap" for qualia (Levine 1983). Some say that the explanatory gap is unbridgeable and that the proper conclusion to draw from it is that there is a corresponding gap in the world. Experiences and feelings have irreducibly subjective, non-physical qualities (Jackson 1993, Chalmers 1996). Others take essentially the same position on the gap while insisting that this does not detract from a purely physicalist view of experiences and feelings. What it shows rather is that some physical qualities or states are irreducibly subjective entities (Searle 1992). Others hold that the explanatory gap may one day be bridged but we currently lack the concepts to bring the subjective and objective perspectives together. On this view, it may turn out that qualia are physical, but we currently have no clear conception as to how they could be (Nagel 1974). Still others adamantly insist that the explanatory gap is, in principle, bridgeable but not by us or by any creatures like us. Experiences and

feelings are as much a part of the physical, natural world as life, digestion, DNA, or lightning. It is just that with the concepts we have and the concepts we are capable of forming, we are cognitively closed to a full, bridging explanation by the very structure of our minds (McGinn 1991).

Another view that has been gaining adherents of late is that there is a real, unbridgeable gap, but it has no consequences for the nature of consciousness and physicalist or functionalist theories thereof. On this view, there is nothing in the gap that should lead us to any bifurcation *in the world* between experiences and feelings on the one hand and physical or functional phenomena on the other. There aren't two sorts of natural phenomena: the irreducibly subjective and the objective. The explanatory gap derives from the special character of phenomenal *concepts*. These concepts mislead us into thinking that the gap is deeper and more troublesome than it really is.

On one version of this view, phenomenal concepts are just indexical concepts applied to phenomenal states via introspection (see Lycan 1996). On an alternative version of the view, phenomenal concepts are very special, first-person concepts different in kind from all others (see Tye forthcoming (b)). This response to the explanatory gap obviously bears affinities to the second physicalist response I sketched in Section III to the Knowledge Argument.

There is no general agreement on how the gap is generated and what it shows.

VI. Qualia and Introspection

In the past, philosophers have often appealed directly to introspection on behalf of the view that qualia are intrinsic, non-intentional features of experiences. Recently, a number of philosophers have claimed that introspection reveals no such qualities (Harman 1990, Dretske 1995, Tye 1995). Suppose you are facing a white wall, on which you see a bright red, round patch of paint. Suppose you are attending closely to the color and shape of the patch as well as the background. Now turn your attention from what you see out there in the world before you to your visual experience. Focus upon *your awareness of* the patch as opposed to *the patch* of which you are aware. Do you find yourself suddenly acquainted with new qualities, qualities that are intrinsic to your visual experience in the way that redness and roundness are qualities intrinsic to the patch of paint? According to some philosophers, the answer to this question is a resounding ‘No’. As you look at the patch, you are aware of certain features out there in the world. When you turn your attention inwards to your experience of those features, you are aware of the *very same* features together with the fact that your mental state is representing them; no new features of your experience over and above its representing red, round, etc. are revealed. In this way, your visual experience is transparent or diaphanous. When you try to examine it, you see right though it, as it were, to the qualities you were experiencing all along in being a subject of the experience, qualities your experience is *of*.

This point holds good even if you are hallucinating and there is no real patch of paint on the wall before you. Still you have an experience *of* there being a patch of paint out there with a certain color and shape. It's just that this time your experience is a misrepresentation. And if you turn your attention inwards to

your experience, you will 'see' right through it again to those very same qualities.

These observations suggest that qualia, the immediately 'felt' qualities of experiences of which we are cognizant when we attend to them introspectively, are *representational* qualities -- qualities like representing red, representing round, representing a red, round shape, and so on. Not everyone agrees that this is what introspection shows (see Block 1991). Perhaps qualia are not presented to us in introspection *as* intrinsic, non-intentional features of our experiences. Still it does not follow from this that we are not introspectively acquainted with intrinsic qualia at all. For we do know on the basis of introspection what it is like to undergo a visual experience of blue, say. So, if what a state is like is a matter of which intrinsic, non-intentional features it tokens, then obviously we are introspectively aware of such features (in the de re sense of 'of'). On this view, whether qualia are intrinsic, non-intentional features of experiences is a theoretical matter. Introspection does not settle the matter one way or the other.

VII. Representational Theories of Qualia

Talk of the ways things look and feel is intensional. If I have a red after-image as a result of a flashbulb going off, the spot I 'see' in front of the photographer's face looks red, even though there is no such spot. If I live in a world in which all and only things that are purple are poisonous, it is still the case that an object that looks purple to me does not thereby look poisonous (in the phenomenal sense of 'looks'). If I feel a pain in a leg, I need not even have a leg. My pain might be a pain in a phantom limb. Facts such as these have been taken to provide further support for the contention that qualia are representational qualities.

If qualia are indeed representational, an important question arises: which aspects of the representational content of an experience are relevant to its phenomenal character, to what it is like to have the experience? Obviously not all aspects of content are phenomenally relevant. If you and I see a telescope from the same viewing angle, for example, then even if I do not recognize it as a telescope and you do (so that our experiences differ representationally at this level), the way the telescope *looks* to both of us is likely pretty much the same (in the phenomenal sense of 'looks'). Likewise, if a child is viewing the same item from the same vantage point, her experience will likely be pretty similar to yours and mine too. Phenomenally, our experiences are all very much alike, notwithstanding certain higher-level representational differences. This, according to some representationalists, is because we all have experiences that represent to us the same 3-D surfaces, edges, colors, and surface-shapes plus a myriad of other surface details.

The representation we share here has a content much like that of the 2 1/2-D sketch posited by David Marr in his famous theory of vision (1982) to which further shape and color information has been appended (for details, see Tye 1995). This content is plausibly viewed as nonconceptual. It forms the output of the early, largely modular sensory processing and the input to one or another system of higher-level cognitive processing. Representationalists sometimes claim that it is here at this level of content that qualia are to be found (see Dretske 1995, Tye 1995; for an opposing representational view, see McDowell 1994).

Representationalists about qualia are typically also externalists about representational content. On this view, what a given experience represents is metaphysically determined at least, in part, by factors in the external environment. Thus, it is usually held, microphysical twins can differ with respect to the representational contents of their experiences. If these differences in content are of the right sort then, according to the wide representationalist, microphysical twins cannot *fail* to differ with respect to the phenomenal character of their experiences. What makes for a difference in representational content in microphysical duplicates is some external difference, some connection between the subjects and items in their respective environments. The generic connection is sometimes called 'tracking', though there is no general agreement as to in what exactly tracking consists.

On wide representationalism, qualia (like meanings) ain't in the head. The classic, Cartesian-based picture of experience and its relation to the world is thus turned upside down. Qualia are not intrinsic qualities of inner ideas of which their subjects are directly aware, qualities that are necessarily shared by internal duplicates however different their environments may be. Rather, they are extrinsic qualities fixed by certain external relations between individuals and their environments.

Representationalism, as I have presented it so far, is an identity thesis with respect to qualia: qualia are supposedly one and the same as certain representational qualities. Sometimes a weaker supervenience thesis is adopted, according to which it is metaphysically necessary that experiences alike with respect to their representational contents are alike with respect to their qualia. Obviously, the supervenience thesis leaves open the further question as to the essential nature of qualia.

Objections to representationalism often take the form of putative counter-examples. One class of these consists of cases in which, it is claimed, experiences have the same representational content but different phenomenal character. Christopher Peacocke adduces examples of this sort in his 1983. According to some (e.g., Block 1990, Shoemaker forthcoming), the Inverted Spectrum also supplies an example that falls into this category. Another class is made up of problem cases in which allegedly experiences have different representational contents (of the relevant sort) but the same phenomenal character. Ned Block's Inverted Earth example (1990) is of this type. The latter cases only threaten strong representationalism, the former are intended to refute representationalism in both its strong and weaker forms. Counter-examples are also sometimes given in which supposedly experience of one sort or another is present but in which there is no state with representational content. Swampman (Davidson 1986) -- the molecule by molecule replica of one of us , formed accidentally by the chemical reaction that occurs in a swamp when a partially submerged log is hit by lightning -- is one such counter-example, according to some philosophers. But there are more mundane cases. Consider the exogenous feeling of depression. That, it may seem, has no representational content. Cases of the third sort, depending upon how they are elucidated further, can pose a challenge to either strong or weaker versions of representationalism.

I lack the space to go through all these objections. I shall discuss briefly just one: Inverted Earth. Inverted Earth is an imaginary planet, on which things have complementary colors to the colors of their counterparts on Earth. The sky is yellow, grass is red, ripe tomatoes are green, and so on. The inhabitants of Inverted Earth undergo psychological attitudes and experiences with inverted intentional contents

relative to those of people on Earth. They think that the sky is yellow, see that grass is red, etc. However, they call the sky ‘blue’, grass ‘green’, ripe tomatoes ‘red’, etc. just as we do. Indeed, in all respects consistent with the alterations just described, Inverted Earth is as much like Earth as possible.

In Block's original version of the tale, mad scientists insert color-inverting lenses in your eyes and take you to Inverted Earth, where you are substituted for your Inverted Earth twin or doppelganger. Upon awakening, you are aware of no difference, since the inverting lenses neutralize the inverted colors. You think that you are still where you were before. What it is like for you when you see the sky or anything else is just what it was like on earth. But after enough time has passed, after you have become sufficiently embedded in the language and physical environment of Inverted Earth, your intentional contents will come to match those of the other inhabitants. You will come to believe that the sky is yellow, for example, just as they do. Similarly, you will come to have a visual experience that represents the sky as yellow. For the experiential state you now undergo, as you view the sky, is the one that, in you, now normally tracks yellow things. So, the later you will come to be subject to inner states that are intentionally inverted relative to the inner states of the earlier you, while the phenomenal aspects of your experiences will remain unchanged. It follows that strong representationalism of the externalist sort is false.

Perhaps the simplest reply that the strong representationalist can make with respect to this objection is to deny that there really is any change in normal tracking with respect to color, at least as far as your experiences go. "Normal", after all, has both teleological and nonteleological senses. If what an experience normally tracks is what nature designed it to track, what it has as its biological purpose to track, then shifting environments from Earth to Inverted Earth will make no difference to normal tracking and hence no difference to the representational contents of your experiences. The sensory state that nature designed in your species to track blue in the setting in which your species evolved will continue to do just that even if through time, on Inverted Earth, in that alien environment, it is usually caused in you by looking at yellow things.

The suggestion that tracking is teleological in character, at least for the case of basic experiences, goes naturally with the plausible view that states like feeling pain or having a visual sensation of red are phylogenetically fixed (Dretske 1995). However, it encounters serious difficulties with respect to the Swampman case mentioned above. On a cladistic conception of species, Swampman is not human. Indeed, lacking any evolutionary history, he belongs to no species at all. His inner states play no teleological role. Nature did not design any of them to do anything. So, if phenomenal character is a certain sort of teleo-representational content, then Swampman has no experiences and no qualia.

There are alternative replies available to the strong representationalist (see Lycan 1996, Tye 1998) in connection with the Inverted Earth problem. These involve either denying that qualia do remain constant with the switch to Inverted Earth or arguing that a non-teleological (but still wide) account of sensory content may be elaborated, under which qualia stay the same.

VIII. Which Creatures Undergo States with Qualia?

Do frogs have qualia? Or fish? What about honey bees? Somewhere down the phylogenetic scale phenomenal consciousness ceases. But where? It is sometimes supposed that once we begin to reflect upon much simpler beings than ourselves -- snails, for example -- we are left with nothing physical or structural that we could plausibly take to help us determine whether they are phenomenally conscious (Papineau 1994). There is really *no* way of our knowing if spiders are subject to states with qualia, as they spin their webs, or if fish undergo any phenomenal experiences, as they swim about in the sea.

Representationalism has the beginnings of an answer to the above questions. If qualia are, by their very nature, qualities of states that carry information about certain features, internal or external, states that form the outputs of sensory modules and stand ready and available to make a direct difference to beliefs and desires, then creatures that are incapable of reasoning, of changing their behavior in light of assessments they make, based upon information provided to them by sensory stimulation of one sort or another, are not phenomenally conscious. Tropistic organisms, on this view, feel and experience nothing. They have no qualia. They are full-fledged unconscious automata or zombies, rather as blindsight subjects are restricted unconscious automata or partial zombies with respect to a range of visual stimuli.

Consider, for example, the case of plants. There are many different sorts of plant behavior. Some plants climb, others eat flies, still others catapult out seeds. Many plants close their leaves at night. The immediate cause of these activities is something internal to the plants. Seeds are ejected because of the hydration or dehydration of the cell walls in seed pods. Leaves are closed because of water movement in the stems and petioles of the leaves, itself induced by changes in the temperature and light. These inner events or states are surely not phenomenal. There is nothing it is like to be a Venus Fly Trap or a Morning-Glory.

The behavior of plants is inflexible. It is genetically determined and, therefore, not modifiable by learning. Natural selection has favored the behavior, since historically it has been beneficial to the plant species. But it need not be now. If, for example, flies start to carry on their wings some substance that sickens Venus Fly Traps for several days afterwards, this will not have any effect on the plant behavior with respect to flies. Each Venus Fly trap will continue to snap at flies as long as it has the strength to do so.

Plants do not learn from experience. They do not acquire beliefs and change them in light of things that happen to them. Nor do they have any desires. To be sure, we sometimes speak as if they do. We say that the wilting daffodils are just begging to be watered. But we recognize full well that this is a harmless facon de parler. What we mean is that the daffodils *need* water. There is here no goal-directed behavior, no purpose, nothing that is the result of any learning, no desire *for* water.

Plants, on the representational view, are not subject to any qualia. Nothing that goes on inside them is poised to make a direct difference to what they believe or desire, since they have no beliefs or desires.

Reasoning of the above sort can be used to make a case that even though qualia do not extend to plants and paramecia, qualia are very widely distributed in nature (see Tye 1997). Of course, such a case

requires decisions to be made about the attribution of beliefs and desires to much simpler creatures. And such decisions are likely to be controversial in some cases. Moreover, representationalism itself is a very controversial position. The general topic of the origins of qualia is not one on which philosophers have said a great deal.

Epiphenomenalism

Epiphenomenalism is the view that mental events are caused by physical events in the brain, but have no effects upon any physical events. Behavior is caused by muscles that contract upon receiving neural impulses, and neural impulses are generated by input from other neurons or from sense organs. On the epiphenomenalist view, mental events play no causal role in this process. They are like a steam whistle that contributes nothing to the work of a locomotive (Huxley, 1874). Mental events do not affect the brain activity that produces them "any more than a shadow reacts upon the steps of the traveller whom it accompanies" (James, 1879).

Epiphenomenalism arose in a 19th Century context in which a dualistic view of mental events was assumed to be correct. The first part of our discussion -- Traditional Arguments -- will be phrased in a style that reflects this dualistic presupposition. By contrast, many contemporary discussions work within a background assumption of the preferability of materialist monism. One might have supposed that this position would have put an end to the need to investigate epiphenomenalism; but, as we shall see under Arguments in the Age of Materialism, such a supposition is far from being the case. A brief outline of both discussions follows.

Many philosophers recognize a distinction between two kinds of mental events. (A) The first goes by many names, e.g., phenomenal experiences, occurrences of qualitative consciousness, the what-it-is-like of experience, qualia. Pains, colors of afterimages, timbres of auditory events, and the qualities of the experience of odors and tastes, can serve as examples. (B) Mental events of the second kind are occurrent propositional attitudes, e.g., (occurrent) beliefs and desires. Arguments about epiphenomenalism may concern either type of mental event, and it should not be assumed that an argument given for one type can be rephrased without loss for the other. The two types can often be connected, however, through beliefs that one has one's qualia. Thus, if it is held that pains have no physical effects, then one must say either (i) pains do not cause beliefs that one is in pain, or (ii) beliefs that one is in pain are epiphenomenal. For, if pains caused beliefs that one is in pain, and the latter had physical effects, then pains would, after all, have effects in the physical world (albeit indirectly). But epiphenomenalism says mental events have *no* effects in the physical world.[1]

Traditional Arguments (A) Pro

The central motivation for epiphenomenalism lies in the premise that all physical events have sufficient causes that lie within the class of physical events. If a mental event is something other than a physical event, then for it to make any causal contribution of its own in the physical world would require a violation of physical law. Descartes' (1649) interactionist model proposed that nonphysical events could cause small changes in the shape of the pineal gland. But such nonphysical effects, however slight, would mean that the physical account of motion is *false* -- for that account says that there will be no such change of shape unless there is a *physical* force that causes it.

One may try to rescue mental efficacy by supposing that whenever there is a mental effect in the physical world there is *also* a physical force that is a sufficient cause of the effect. This view, however, both offends Occamist principles and fails to satisfy the leading anti-epiphenomenalist intuition, namely, that the mental *makes a difference* to the physical, i.e., that it leads to behavior that would not have happened in absence of the mental. The view also leads to an epistemological problem: If there is always a sufficient physical cause for behavior, then one could never be in a position where one *needs* to suppose there is anything further. Thus, on the assumption of physical sufficiency, there could never be any reason to introduce mental causes into one's account of behavior.

Many contemporary thinkers would respond to the central motivation for epiphenomenalism by denying its dualistic presupposition, i.e., by holding that mental events are identical with physical events, and may therefore have physical effects. Discussion of this type of response will be given below in the Remarks on Kim's Way Out. Here it may be observed, however, that the argument stated in the previous two paragraphs is not supposed to be an argument for dualism, but only for adopting epiphenomenalism, once dualism is accepted.

Further support for epiphenomenalism can be derived from the fact, noted by Wilhelm Wundt (1912),

that "each simple sensation is joined to a very complicated combination of peripheral and central nerve processes", together with the fact that the causes of behavior are likewise complex neural events. This latter fact makes it natural to look for complex events throughout the causal chain leading to behavior; and these can be found in the neural events that are required for the occurrence of simple sensations. The sensations themselves could not contribute to behavior without first having neural effects that are more complex than themselves. Thus an anti-epiphenomenalist stance would require us to prefer the hypothesis that simple sensations cause (relatively) complex neural events over the hypothesis that complex neural events (that are required in any case for the causation of sensations) are adequate to cause the neural events required for the causation of behavior.

Traditional Arguments (B) Con (with Epiphenomenalists' Replies)

(1) Obvious Absurdity

Epiphenomenalism is absurd; it is just plain obvious that our pains, our thoughts, and our feelings make a difference to our (evidently physical) behavior; it is impossible to believe that all our behavior could be just as it is even if there were no pains, thoughts, or feelings. (Taylor, 1963 and subsequent editions, offers a representative statement.)

This argument is surely the briefest of those against epiphenomenalism, but it may have been more persuasive than any other. Epiphenomenalists, however, can make the following reply. First, it can never be obvious what causes what. Animated cartoons are full of causal illusions. Falling barometers are regularly followed by storms, but do not cause them. More generally, a regularity is causal only if it is not explained as a consequence of underlying regularities. It is part of epiphenomenalist theory, however, that the regularities that we observe to hold between mental events and actions can be explained by underlying regularities. Schematically, suppose physical event P1 causes both mental event M and physical successor P2, as in Figure 1.

```
 M
 |
 P1 --> P2 --> P3 --> ...

(Figure 1)
```

Suppose there is no other cause of M, and no other cause of P2. Then every M will be followed by P2, yet the cause of P2 will be adequately found in P1. It is true that, under the assumptions stated, the counterfactual, "If M had not occurred, then P2 would not have occurred" holds; but then, so may "if the barometer had not fallen, the storm would not have occurred." The moral to be drawn is that causation may imply that certain counterfactuals hold, but the holding of counterfactuals is not enough to show causation. So, the fact that under normal conditions, some of our actions would not have occurred unless

we had had certain mental events cannot show that those actions are caused by our mental events (rather than being caused by the physical causes of those mental events).

It is often said that pains cause withdrawals of affected parts of the body. In extreme cases, however -- for example in a case of touching a hot stove -- it can be observed that the affected part is withdrawn *before* the pain is felt. These cases cannot show that pain never causes withdrawals, but they do show that pain is not necessary as a cause of withdrawals. In less extreme cases, it is open to the epiphenomenalist to hold that the causal order is the same as in the extreme cases (i.e., some physical event, P1, causes both withdrawal and pain) but is not ordinarily recognized to be so.

(2) Natural Selection

The development of consciousness must be explainable through natural selection. But a property can be selected for only if it has an effect upon organisms' behavior. Therefore, consciousness (both qualia and intentional states) must have effects in behavior, i.e., epiphenomenalism is false. (Today, this argument is generally associated with Popper and Eccles, 1977. It is an old argument, however, and clear statements of it were offered by James (1879) and by Romanes in 1882 (see Romanes, 1896).)

According to the same biology that embraces natural selection, however, behavior has muscular causes, which in turn have neural causes. Barring neural events that are inexplicably in violation of biological constraints on their conditions of activation, there must be an adequate physical cause of every link in the causal chain leading to behavior. Thus, it is easily understood how certain kinds of neural events can be selected for. Epiphenomenalists hold that conscious events are effects of (certain) neural events. Thus, it fits well in their view that we have the conscious events we do because the neural causes of these events have been selected for. Indeed, if neural causes of behavior are selected for, and are sufficient causes, there *cannot* be any *further* effect attributed to natural selection.

William James (1879; 1890) offered an intriguing variant of the argument from natural selection. If pleasures and pains have no effects, there would seem to be no reason why we might not abhor the feelings that are caused by activities essential to life, or enjoy the feelings produced by what is detrimental. Thus, if epiphenomenalism (or, in James' own language, automaton-theory) were true, the felicitous alignment that generally holds between affective valuation of our feelings and the utility of the activities that generally produce them would require a special explanation. Yet on epiphenomenalist assumptions, this alignment could not receive a genuine explanation. The felicitous alignment could not be selected for, because if affective valuation had no behavioral effects, misalignment of affective valuation with utility of the causes of the evaluated feelings could not have any behavioral effects either. Epiphenomenalists would simply have to accept a brute and unscientific view of pre-established harmony of affective valuation of feelings and the utility of their causes.

Epiphenomenalists can meet James' argument, however, by supposing that both the pleasantness of pleasant feelings and the feelings themselves depend on neural causes (and analogously for painfulness and disliked qualities). So long as both types of neural events are efficacious in the production of

behavior, their combination can be selected for, and thus the felicitous alignment of feelings with evaluation can be explained. Moreover, the supposition that the neural causes of both evaluation and feeling qualities should have behavioral effects is independently plausible: on grounds of natural selection, there should be both a preference system for quick action and a system that fosters discriminability, for use in longer term planning; and these must, in general, work together in a successful organism.

(3) Knowledge of Other Minds

Our reason for believing in other minds is inference from behavioral effects to mental event causes. But epiphenomenalism denies such a causal connection. Therefore, epiphenomenalism implies the (exceedingly implausible) conclusion that we do not know that others have mental events. (Jackson, 1982, replies to this and several other arguments against epiphenomenalism. The argument is stated, and accepted, by Benecke, 1901.)

The first premise of this argument is a widely held dogma, but epiphenomenalists can deny it without evident absurdity. It is perfectly obvious to everyone that the bodies of human beings are very much alike in their construction, and it requires no sophisticated reasoning to infer that if others are made like me, they probably hurt when affected like me, e.g., when their bodies are stuck with pins, beaten, cut and so on. There is no principle that makes an inference from similar effects to similar causes more secure than an inference from similar causes to similar effects; on the contrary, the latter inference is more secure, because there can sometimes be different causes of undetectably similar effects. Thus, an inference to other minds that is allowed by epiphenomenalism must be at least as strong as the inferential route to other minds with which it is incompatible.

(4) Self-stultification

The most powerful reason for rejecting epiphenomenalism is the view that it is incompatible with knowledge of our own minds -- and thus, incompatible with knowing that epiphenomenalism is true. (A variant has it that we cannot even succeed in referring to our own minds, if epiphenomenalism is true.) If these destructive claims can be substantiated, then epiphenomenalists are, at the very least, caught in a practical contradiction, in which they must claim to know, or at least believe, a view which implies that they can have no reason to believe it. (Many authors offer this objection in one version or another. A full statement of this argument, and several others concerning epiphenomenalism, can be found in Chalmers, 1996.)

The argument that is given to support the destructive claims is that (i) knowledge of one's mental events requires that these events cause one's knowledge, but (ii) epiphenomenalism denies physical effects of mental events. So, either we cannot know our own mental events, or our knowledge of them cannot be what is causing the plainly physical event of our saying something about our mental events. Thus, suppose S is an epiphenomenalist, and that S utters "I am in terrible pain." S is committed to the view that the pain does not cause the utterance. But then, it seems, S would be making the same utterance whether

or not a pain were occurring. If this is so, then S's testimonies about S's own pains are worthless -- both to us and to S. They cannot be taken to represent any knowledge about pains on S's part (if S's epiphenomenalist view is true). In fact, on an epiphenomenalist view, all the arguments for epiphenomenalism and rebuttals to counterarguments we have reviewed might be given even if we were all zombies -- i.e., even if we were all possessed of physical causes of our utterances and completely devoid of any mental life whatsoever.

The argument that epiphenomenalism is self-stultifying in the way just described rests on the premise that knowledge of a mental event requires causation by that mental event. But epiphenomenalists may reject that premise without absurdity. One way of seeing how to do this involves considering the interactionist diagram in Fig.2, which shows P1 as directly causing M but not P2, and M directly causing P2. (Directly causing is an intransitive relation. Causation (when used without modifier) is transitive: events are causally related if there is a chain of direct causes, however long, that connects them.)

```
M
 \
| C
   \
P1  P2 --> P3 --> ....
```

(Figure 2)

Now consider P3, which is directly caused by P2 and which we will assume to cause (directly or indirectly) further behavior such as S's utterance of "I am in terrible pain". P3 is not directly caused by M. Does it convey knowledge of M? If we answer negatively, on the ground that P3 is not directly caused by M, we will be rejecting interactionism for virtually the same reason that epiphenomenalism is thought to be unacceptable. Since this is an extremely implausible stance, let us take it that P3 does convey knowledge of M. But what property does P3 actually have that makes it a case of conveying knowledge of M? Epiphenomenalists will wish to point out that P3 does not have any property that contains information as to how it was caused. Looking backward from P3, so to speak, one cannot tell whether it was indirectly caused by M (as in the interactionistic Fig. 2) or indirectly caused by M's cause (as in the epiphenomenalistic Fig. 1). There is, however, a property that P3 does have that is intuitively strongly connected to its conveying knowledge of M -- namely, that it would not be occurring unless M had recently occurred. But P3 has this property on epiphenomenalist and interactionist views alike. Thus, if not occurring unless M has recently occurred is the property that is responsible for P3's conveying knowledge of M, epiphenomenalists have as much right as anyone to claim that P3 conveys knowledge of M, and they are not debarred from knowing what they claim to know.

Critics of epiphenomenalism can of course point out that there is a property that interactionism, but not epiphenomenalism, assigns to P3 -- namely, the property of being indirectly caused by M. Epiphenomenalists, however, are likely to think that the intuitive connection between this property and knowledge is much weaker than that between knowledge of M and the fact that P3 would not be occurring unless M had recently occurred. In fact, they may hold that the relevance of indirect causation

is exhausted by its ensuring that P3 would not occur unless M had recently occurred. They can then reiterate that there is another way of ensuring that this condition holds, namely, the set of relations, diagrammed in Fig. 1, that is affirmed by epiphenomenalism.

The foregoing way of responding to the self-stultification argument is further explained and defended in Robinson (1982b). An alternative response can be found in Chalmers (1996). Chalmers' property-dualistic view holds that there is more to a person than just a brain and a body. It allows for persons to be directly acquainted with experiences, and it is this direct acquaintance, rather than any causal relation, that justifies our beliefs about experiences. On this view, experiences are partially constitutive of beliefs about experiences, and "the justification of my belief [about experiences] accrues not just in virtue of my physical features but in virtue of some of my nonphysical features -- namely the experiences themselves" (Chalmers, 1996, p. 198). In supplying non-causal relations to support the claim to knowledge of experiences, this view disconnects the knowledge question from the question of how things stand causally, and thus avoids the self-stultification argument.

Arguments in the Age of Materialism

One might have thought that if the mental and the physical are identical, there could be no room for epiphenomenalistic questions to arise. Behavior is caused by muscular events, and these are caused by neural events. Mental events will be identical with some of these neural events; so whatever effects these neural events have will be effects of mental events, and mental events will make a causal contribution to, i.e., will "make a difference" to our behavior.

Questions about epiphenomenalism, however, arise the moment any distinction is made between the mental properties and the physical properties of an event. There are several ways of doing this within a broadly materialist monism. The following discussion will briefly indicate two ways in which this distinction can be made, and the kind of epiphenomenalistic questions that ensue.

It should be noted that most recent writers take a somewhat dogmatic position against epiphenomenalism. They presume that epiphenomenalism is to be avoided, and they go to great lengths to try to show that they have avoided incurring that anathema, despite maintaining the sufficiency of physical causation in conjunction with some kind of distinction between the mental and the physical.

Two Routes to Puzzlement: Anomalous Monism and Externalism

(1) Donald Davidson's (1970) anomalous monism holds that (i) each mental event is identical with a physical event, but (ii) there are no psychophysical laws. To introduce a convenient example, it is plausible that each person's (occurrent) belief that the Mona Lisa is in the Louvre is identical with some physical event in that person's brain; but there is no one physical brain-event type such that all who hold that belief have that kind of brain event. Now suppose Jones believes that the Mona Lisa is in the Louvre, and is heading toward the Louvre. What causes Jones's motion? Let us first fix a background that consists

of neural events that are identical with Jones's desire to see the Mona Lisa, Jones's understanding of certain maps of Paris, and so forth. These neural events interact with the neural events that are identical with Jones's belief about Mona's location, with neural events that are identical with Jones's perceptions of sidewalks, obstacles, street signs, and so on, and these neural events eventually produce the muscular events that cause Jones's motion toward the Louvre. It seems that if we fill in this sketch, we will have a complete causal explanation of Jones's progress. But such a completely filled-in sketch will contain reference only to neural events, and the mental types with which they are identical will not be so much as mentioned. Moreover, the denial of psychophysical laws means that there is no law-like connection between any psychological type and the neural types that do the causal work. In short, despite the identity of mental and physical events, the mental character of Jones's brain events seems to have nothing to do with where Jones goes.

(2) The same point can be reached through a somewhat different route. Many philosophers hold an *externalist* view of intentionality, according to which intentionality requires representation, and representation depends on circumstances external to the body of the representing subject. (To illustrate with Putnam's (1975) famous example from Twin Earth, what a thought that S might express by "This is water" is actually about depends on what the transparent, tasteless liquid in S's environment actually is.) It seems, however, that the causal determinants of S's behavior can depend only on events occurring inside S's body. Thus, if externalism is right, what S does cannot depend on S's thoughts.

This conclusion is compatible with holding that a proper *description* of S's behavior should refer to circumstances external to S. For example, describing S as *reaching for a glass of water* may not be appropriate unless S believes the glass contains water; and that this is what S believes may depend on circumstances external to S. But then, it is at least tempting to conclude that it cannot be S's belief (at least not S's belief fully described in intentional terms) that is causing the extension of S's arm toward the glass. After all, S's twin-earth double has, in some sense, a different belief (one that refers to XYZ) but the internal bodily story of the causation of the double's arm-extension will be exactly the same as the story for S (up to substitution of XYZ in the double's body wherever S has an H_2O molecule).

Kim's Way Out

In a well-known series of essays, now published as Kim (1993), Jaegwon Kim has offered a view that attempts to reconcile the closure of the physical (the view that every physical event has a set of causes that are both sufficient and physical) with our intuitions about the efficacy of the mental. It is not appropriate here to attempt a complete discussion of Kim's carefully drawn distinctions and thorough argumentation. We may, however, describe a crude example (not Kim's own) and express some of Kim's cardinal points in its terms.

Consider the world of pumps. These come in different kinds -- piston, diaphragm, rotary, etc. The status of an object as a pump arguably depends on its being part of a larger system. For example, we can use a fan to pump some noxious gas from one room to another, or to the outside of a building; but if we set a fan on the lawn, it may beat the air, but is not (functioning as) a pump. Pumps have causal properties --

e.g., they can move fluids. They have these causal properties in virtue of the properties of their parts; e.g., the imperviousness (to gas molecules) and angle of the fan blade cause gas molecules that hit it to move in certain directions.

The properties just listed match properties of mental events, on many views of the latter. Thus, the same belief (i.e., belief in the truth of the same proposition) may be realized as different neural states in different people (or the same person at different times); an occurrence of a belief in a (part of a) brain would not have the causal properties it is often thought of as having unless it were surrounded by a functioning whole brain and body; and a belief would not have the causal properties it is often thought of as having unless it had a neural constitution that could affect other neural (and eventually muscular) events.

Now, let us imagine a "pump epiphenomenalist" (P-Eist), who argues as follows. "Pumps have no efficacy. Of course, objects are caused to be pumps, i.e., their being pumps is a consequence of their parts having the properties they have and standing in the relations in which they stand. But all the causal work of pumps is explained by the properties and relations of the parts. It would be ludicrous to say that the movement of fluids has *two* causes, i.e., the push of the blades *and* the pumping. Explanation of the movements of fluids in terms of such things as rigidity and motion of the pump's parts *has* to be mentioned in any full account of those movements, and this kind of explanation explains everything that needs to be explained; thus the explanation in terms of rigidity and motion of the pump's parts *excludes* the property of being a pump from any explanatory role. Our intuition that pumps move fluids is just an illusion. Being a pump is a mere epiphenomenal property."

What the P-Eist says about pumps is in every way correct -- except for the conclusion. Thus, if mental event properties are analogous to the property of being a pump, then all the reasons that lead to epiphenomenalism can be granted, without granting the epiphenomenalist conclusion. Or, to put the matter somewhat differently, if epiphenomenalism leaves mental event properties no worse off than the property of being a pump, then we can accept epiphenomenalism of mental event properties with equanimity. Despite the points made in the preceding paragraph, we will not feel that we are making a mistake when we say that pumps move fluids; and no more should we feel that we are making a mistake if we say that S reaches for the glass because S believes it contains water.

Remark on Kim's Way Out

As Kim is well aware, this attractive solution depends on a key point in the analogy between mental properties and the property of being a pump. We feel it is idle to deny that pumps move fluids because pumps are *realized* in (or by) the system of parts whose properties and relations figure in the fully detailed causal explanation of the movement of fluids. Because there can be many kinds of pumps, we cannot *identify* being a pump with any of the configurations that realize pumps. But we have insight into why it is that a given configuration of parts, surrounded by a certain kind of system, is *necessarily* a pump. If we can say that what causes the movement of certain fluids *had* to be a pump, the claim that being a pump has nothing to do with the movement would seem to be merely a tendentious and

misleading description of the circumstances.

Now, there are some mental properties for which it is plausible that the key analogy just described holds. These are the properties for which functionalism is most plausible, e.g., beliefs and desires. That is, it does not seem out of the question that a view can be sustained according to which S's neural condition at time t, in S's surrounding's at t (and, perhaps, given S's history) *necessarily constitutes* S as a believer of p, or a desirer of q. If such an account can be made out, then there is a robust sense to the idea that beliefs and desires are *realized by* the physical conditions just listed; that they are thus no worse off than pumps in the realm of efficacy; and that there will be no violation of our intuitions that S's actions occur because of what S believes and desires.

But there are other mental properties that resist the kind of story that seems plausible for beliefs and desires. As Kim again explicitly recognizes (1993, p. 366), these are the properties that have long caused difficulties for functionalism, namely, the qualities of phenomenal experiences such as pains, itches, tastes, smells, afterimages, and so on. The "explanatory gap" (Levine, 1983) or "unintelligibility" (Robinson, 1982a) in the connection between neural events and phenomenal qualities can be otherwise expressed as our inability to see any necessity in that connection. We are unable to understand why it should be that a series of neural activations occurring in various degrees of intensity and temporal relations should always be accompanied by pain, or itch, or, indeed, by any phenomenal quality whatever. Inability to see any such necessity is, of course, not a proof that such a necessity does not obtain. Nonetheless, absent insight into the necessity of the connection between neural properties and qualitative properties, we are arguably in an *explanatory* position similar to traditional epiphenomenalism. That is, we will have a sufficient explanation of behavioral reactions to stimuli that invokes exclusively neural properties. In addition, we may hold the view that these neural properties are necessarily connected to qualitative properties; but, lacking explanation of this necessity, this connection will contribute no understanding of how qualitative properties could make a difference to behavior. Because this difficulty has not been removed in the case of qualia, the success or failure of the previously discussed Traditional Arguments remains relevant to contemporary thinking about epiphenomenalism.

Epiphenomenalism and Intrinsic Properties

Frank Jackson (1982) has given an epiphenomenalistic argument that has spawned lively responses from many quarters. This argument turns on the concept of physical information, where "physical information" is information about ourselves and our world of the kind that is obtainable in the physical, chemical, and biological sciences. In Jackson's argument, a brilliant scientist, Mary, has learned all the physical information there is about color vision. Having been confined to a black and white room, however, Mary has never had a color experience. Jackson asks whether Mary will learn anything when she is released from her confinement and thus comes for the first time to have color experiences. It seems compelling that she would learn something; but as she already has all the physical information there is, what she learns must be some other kind of information, which we may call "phenomenal information". This "knowledge argument" has been regarded as a strong reason to accept a dualistic view of our experiences. When combined with the traditional arguments (Pro) given above, it becomes a potent source of support

for epiphenomenalism.

David Lewis (1988) undertakes a thorough response to the knowledge argument. Among Lewis's many considerations, there is one that seeks to enforce a connection between phenomenal information *per se* and epiphenomenalism. According to Lewis's argument, even if one says that phenomenal *events* are identical with physical events, and even if one says that phenomenal events produce physical effects in violation of physical laws, one will still be led to a form of epiphenomenalism if one says there is phenomenal information that is irreducibly different from physical information. To put the argument in ruthlessly summary form, let V1 and V2 be two possibilities for the phenomenal information that one acquires by, and only by, tasting Vegemite. Suppose that P1 is a physical state produced by the taste of Vegemite. That the taste of Vegemite has this physical effect is a piece of physical information. But this same physical information is compatible with two possibilities, (a) V1 is related by a law, L1, to P1; and (b) V2 is related by a different law, L2, to P1. Now, either of these possibilities is compatible with all the physical information we have; i.e., their difference makes no physical difference. Thus, that the phenomenal information in the taste of Vegemite is, say, V1 rather than V2 can make no difference to anything physical, i.e., V1 is epiphenomenal. Lewis's point here is not to argue for or against epiphenomenalism; rather, he assumes epiphenomenalism is false, and uses the fact that the hypothesis of phenomenal information leads to it as an argument against that hypothesis.

Denis Robinson (1993) raises the possibility that Lewis's argument can be extended to produce a far-reaching and puzzling result. Suppose that I1 and I2 are two possibilities for an *intrinsic* property of a basic physical entity, e.g., a quark. Everything relevant to physics can be expressed by the lawlike relations in which quarks stand to fundamental physical objects and properties. Let this set of relations be [S]. It appears that there are two possibilities, (a) I1 is related by a set of laws, [L1], to [S]; or (b) I2 is related by a different set of laws, [L2], to [S]. Either of these possibilities is compatible with all the physics we have, i.e., their difference makes no physical difference. Thus, that the intrinsic property of quarks is, say, I1 rather than I2 can make no difference to physics, i.e., I1 is epiphenomenal. The generalization of this point is that the intrinsic properties of the fundamental objects of physics must be epiphenomenal.

It thus appears that we must either (1) deny that fundamental objects of physics have any intrinsic properties, or (2) deny that Lewis's argument for the connection of phenomenal information with epiphenomenalism is sound, or (3) deny that Lewis's argument can be paralleled in the suggested way for the case of intrinsic physical properties, or (4) admit an epiphenomenalism of intrinsic properties into our view of the basic structure of physical reality.

Bertrand Russell (1927, p. 382) held the view that physical theory can reveal only causal structure, or "formal properties" of matter, and that "by examining our percepts we obtain knowledge which is not purely formal as to the matter of our brains." This idea is taken up sympathetically (with substantial reworking in a quantum mechanical context) by Lockwood (1993). Chalmers (1996) offers a useful discussion of the view, and expresses some sympathy for it. Denis Robinson (1993), however, regards intrinsic similarity of fundamental physical entities as different from similarity of phenomenal properties.

If phenomenal properties are intrinsic properties of fundamental physical objects, and the latter stand in lawlike relations, then lawlike relations will hold between phenomenal properties and some physical occurrences. This conclusion appears to give a causal role to phenomenal properties and thus to suggest a way out of epiphenomenalism. But if intrinsicality carries epiphenomenality, as D. Robinson's extension of Lewis's argument suggests, then this way out of epiphenomenalism would be blocked.

Libet's Unconscious Cerebral Initiatives

Benjamin Libet (1985) argues that experiments done by himself and others shows that certain voluntary actions are preceded by neural events that occur prior to awareness of the intention to act. Interpretation of Libet's results is extremely controversial (see the Open Peer Commentaries following Libet's (1985) target article), and Libet himself does not draw an epiphenomenalistic conclusion. Some philosophers have, however, noted that if Libet's own claims are accepted, then some of our actions are initiated prior to our conscious intention to perform them. If this is correct, then at least in some cases our intuitive judgments that our conscious intentions are causing our movements must be illusory.

Historical Note on Automatism and the Term "Epiphenomenalism"

James Ward's *Encyclopedia Britannica* (Tenth edition, 1902) article, "Psychology", contains the following summary of T. H. Huxley's view: "physical changes are held to be independent of psychical, whereas psychical changes are declared to be their "collateral products." They are called *collateral* products, or "epiphenomena" to obviate the charge of materialism . . . ." McDougall (1911) roundly declares, referring to Huxley, that "to him [the doctrine] owes the name by which it is generally known; for he it was who suggested that the stream of consciousness should be called epiphenomenal, or the epiphenomenon of the brain-process." In Carington (1949), H. H. Price expresses his belief that the term "epiphenomenalism" was introduced by T. H. Huxley.

It is interesting, therefore, that the term "epiphenomenalism" does not occur in Huxley's (1874) essay on our topic; nor have I been able to find it elsewhere in his published work. (Neither does Huxley use the terms "stream of consciousness" or "brain-process".) Of course, it is possible that Huxley made oral use of "epiphenomenalism" in lecturing. This seems unlikely, however, as he had at his disposal another brief term for the view he was concerned to promote, the meaning of which would have been more immediately accessible to most audiences, namely, "automatism". This is the term that occurs in his 1874 essay, which bears the title "On the Hypothesis that Animals are Automata, and its History". Besides containing the analogy of the steam-whistle that contributes nothing to the locomotive's work, this essay compares consciousness to the sound of the bell of a clock that has no role in keeping the time, and treats volition as a symbol in consciousness of the brain-state cause of an action. As Ward correctly noted, nonefficacious mental events are referred to in this essay as "collateral products" of their physical causes. The essay is not solely concerned with animals: to the best of Huxley's judgment, "the argumentation which applies to brutes holds equally good of men".

Huxley and his contemporaries seem to have been impressed by preparations in which frogs had had various portions of their brains removed. Reasoning by analogy with humans lesioned by disease or battle, Huxley finds it plausible that the frogs are not conscious, or not exercising volition; yet when thrown into water, for example, they swim just as well as undamaged frogs. Huxley also discusses at some length the case of a Seargent F., who had sustained a shot that fractured his left parietal bone. Once or twice a month, this soldier would have a day-long bout in which he exhibited complex behavior (e.g., singing, writing a letter, "reloading", "aiming", and "firing" his cane with motions exactly appropriate to a rifle in a skirmish) while being plausibly unconscious, as evidenced by insensitivity to pins and shocks, sound, smell and taste, and to a great extent, vision. Huxley allows that there can be no direct evidence showing that the soldier is conscious or not conscious; but he concludes that he may be devoid of consciousness, while performing his complex and apparently purposeful movements.

Huxley was not alone among 19th century figures who gave vigorous and clear expositions of an epiphenomenalistic view. S. Hodgson (1870), W. K. Clifford (1874) and H. Maudsley (1886) were exponents of the view. Romanes' posthumous (1896) contains an excellent statement of the view, which was first published in the early 1880s; and William James (1879) likewise offers an early clear statement of it. Both Romanes and James follow their statements of the view with arguments against its acceptance.

None of the works just mentioned include the term "epiphenomenalism". I have located three articles in *Mind* in the 1890s that do use the term (the earliest, in 1893, hyphenates it as "epi-phenomenalism"). The earliest occurrence of the term for referring to automatism that I have been able to locate is in William James's *The Principles of Psychology*, first published in 1890. It occurs in his chapter "The Automaton-Theory" once, in scare quotes; the rest of the time, the view is referred to as the "automaton-theory" or the "conscious automaton-theory". James attributes the origination of the view to Shadworth Hodgson, in *The Theory of Practice* (1870). A section of this work titled "Dependence of consciousness on nerve movement" does indeed contain a forthright statement of the view (without "epiphenomenalism", "automatism" or any other "-ism" tag).

Early in his discussion of automatism, James (1890) includes some remarks about his intellectual development, and refers to his early study of medicine. "Epiphenomenon" has a use in this field, meaning a symptom concurrent with, but not causally contributory to, the course of a disease. Some early twentieth century dictionaries list only this meaning of the term; by mid-twentieth century, the focal philosophical meaning is standardly given. My present surmise is that the term "epiphenomenalism" came into philosophy from medicine in the late nineteenth century, possibly, though less certainly, through William James's use of the term in his influential *Principles of Psychology* (1890).

Bibliography

An extensive bibliography is available under the entry for epiphenomenalism in the CD-Rom edition of *The Philosopher's Index*. The list below contains all items referred to in the foregoing article, and a few other sources that offer particularly helpful discussions.

Notes to Epiphenomenalism

Notes

[1.] Strictly speaking, one can distinguish two versions of epiphenomenalism, (a) mental events have no effects; and (b) mental events may have effects on other mental events, so long as the latter do not have any physical effects, nor any effects on further mental events that eventually have any physical effects. Because observing this distinction would contribute nothing but a tedious duplication of arguments that would differ only trivially, it will be ignored in the remainder of the article.

Multiple Realizability

In the philosophy of mind, multiple realizability is the contention that a given mental kind (property, state, event) is realized by distinct physical kinds. The classic example (presented below) is pain: a wide variety of physical states and events, sharing nothing in common at that level of description, can presumably realize the same pain state. This contention served as a premise in the most influential argument against early psychoneural identity theories. It also served indirectly in early arguments for functionalism. More recently, it has been adopted by nonreductive physicalists to challenge all varieties of psychophysical reduction. It has even been employed to challenge the functionalism it initially motivated. A variety of recent reductionist programs have either attacked the argument from multiple realizability to irreducibility or revised aspects of classical reductionism that made the latter susceptible to this challenge. Even the truth of the multiple realizability contention has been questioned.

What is meant by "realization" in this context? Typically a standard characterization is given. An event e's being F realizes e's being G just in case (i) e is F, (ii) e is G, (iii) for all e it is (physically) necessary that if e is F then e is G, and (iv) e's being F explains e's being G. The last condition requires extensive clarification, but the key point is that realization is stronger than "mere" (physical) necessity. This is because some (physically) necessary property connections are not explanatory. It should be noted that this standard characterization does not capture the relation championed by some functionalists, who hold that a physical state can realize a functional state contingently. The appropriate characterization of realization, like that of supervenience in related contexts, remains a contentious matter.

Putnam's Early Arguments

In a series of papers published throughout the 1960s (and reprinted in his 1975 anthology, Hilary Putnam introduced multiple realizability into the philosophy of mind. Against the "brain state theorist," who holds that every mental kind (like pain) is identical to some as-yet-undiscovered neural kind ("C-fiber firing" was a favorite expression), Putnam considers the wide variety of terrestrial creatures seemingly capable of the former. Humans, other primates, other mammals, birds, reptiles, amphibians, and even mollusks (e.g., octopi) seem reasonable candidates for pain-bearing. But then for the brain state theory to be true, there must be some physical-chemical kind common to this wide variety of neural structures, and correlated exactly with each occurrence of the mental kind. This is a necessary condition of the hypothesized type-identity. Comparative neuroanatomy and physiology, facts about convergent evolution, and the corticalization of function (especially sensory function) as cortical mass increases across species all speak against this consequence. Furthermore, early identity theories insisted that these identities, while contingent, hold by virtue of natural (scientific) law. But then any physically possible cognizer (e.g., pain-bearer) must also be capable of that physical-chemical kind. Here the well-known philosophers' fantasies enter the discussion: silicon-based androids, artificially intelligent electronic robots, Martians with green slime pulsating through their heads. Even further, these identity theories were supposed to be completely general: every mental kind was held to be identical to some neural kind. So the critic needed to find only one mental kind realized differently at the physical-chemical level. As Putnam admitted, the early identity theories were empirical hypotheses. But one consequence was "certainly ambitious," and (highly) probably false.

The argument from multiple realizability for functionalism is more indirect. Ned Block and Jerry Fodor (reprinted as Chapter 4 in Fodor 1981)once noted that this feature of the mental shows that any physical type-identity hypothesis will be insufficiently abstract. Functionalism, which seeks to identify mental kinds with functional kinds characterized exhaustively in terms of their causes and effects, seems to be the next level of abstraction up in the property hierarchy from physical mechanisms. Multiple realizability at the level of physical description is a common characteristic of functional kinds like mousetrap and valve lifter. Characterizing mental kinds as functional kinds thus appears to be a reasonable empirical hypothesis in light of multiple physical realizability.

Fodor's Elaboration and the Legacy of Multiple Realizability

One reply a physical type-identity theorist might make identifies mental kinds with the disjunction of the physical kinds realizing it. (Jaegwon Kim once defended this strategy; the article is reprinted as Chapter 8 in Kim 1993.) Putnam dismissed this strategy as unworthy of serious consideration, but Fodor saw the deep difficulty that the required disjunctions create. In Chapter 1 of his (1975) he argued that reductionism imposes too strong a constraint on acceptable theories in special sciences like psychology. Fodor characterized reductionism as the conjunction of "token physicalism" with the claim that there are natural kind predicates in an ideally completed physics corresponding to each natural kind term in any ideally completed special science. (He characterized "token physicalism" as the claim that all events that science talks about are physical events.) Fodor gave reductionists the best-developed theory of reduction

at the time: in essence, Ernest Nagel's (1961) "derivability" account, which "connected" disparate elements of the reduced and reducing vocabularies via "bridge laws" and claimed a reduction when the laws of the reduced theory were derived from the laws of the reducing and the bridge laws. According to Fodor (1975), if reductionism is to establish physicalism, these cross-theoretic bridge laws must establish contingent identities of reduced and reducing kinds. But given multiple realizability, the only way this can obtain is if the physical science constituent of a psychophysical bridge law is a disjunction of all the terms denoting possible physical realizations of the mental kind. Given the extent and variety of the latter, it is overwhelmingly likely that the disjunctive component will not be a kind-predicate, nor the entire statement a law, of any physical science. Multiple realizability demonstrates that the additional component of reductionism (beyond token physicalism) is empirically untenable.

In a pair of famous examples illustrating multiple realizability in special sciences (economics and psychology), Fodor (1981, Chapter 5) implicitly distinguishes two types of the relation. Call the type Putnam emphasized multiple realizability "across physical structure-types." A more radical type would obtain when a token nervous system realizes a given mental kind via distinct neural events at different times. Call this sense multiple realizability "in a token system across times." (These terms are from John Bickle 1998, Chapter 4.) This second sense will typically increase the disjunctive components of psychophysical bridge laws, because there will be a disjunction of physical predicates realizing each mental kind for every token cognizer.

Following Fodor, psychologist Zenon Pylyshyn (1984) used multiple realizability to ground a methodological criticism of reductionism. He describes a pedestrian, having just witnessed an automobile accident, rushing into a nearby phone booth and dialing a 9 and a 1. What will this person do next? Dial another 1, with overwhelming likelihood. Why? Because of a systematic generalization holding between what he recognized, his background knowledge, his resulting intentions, and that action (intentionally described). But we won't discover that generalization if we focus on his neurophysiology and the resulting muscular contractions. That level of explanation is too weak, for it cannot tell us that this sequence of neural events and muscular contractions corresponds to the action of dialing a 1. A given physiological explanation only links one way of learning the emergency phone number to one way of coming to know that an emergency occurred to one sequence of neural events and resulting muscular contractions producing the behavior (nonintentionally described). However, the number of physical events constituting each of these cognitive classes--the learning, the coming to know, and the action of dialing--is potentially unlimited, with the constituents of each class often unrelated to each other at the physiological level of description. This is a consequence of multiple realizability. So if there is a generalization at the higher level of description available for capturing--and in the pedestrian example there surely is--an exclusively reductionist approach to psychological explanation will miss it. Thus because of multiple realizability, reductionism violates a tenet of scientific methodology: seek to capture all capturable generalizations. (Fodor 1975, Chapter 5, and Terence Horgan 1993 have also raised related methodological caveats about reductionism resting ultimately on multiple realizability. Bickle 1998, Chapter 4, has recently responded to these.)

Contemporary nonreductive physicalism is currently the dominant position in Anglo-American philosophy of mind. It accepts without alteration or amendment the multiple realizability challenge to all

versions of reductive materialism. Ernest LePore and Barry Loewer (1989) have recently called the nonidentity of mental content and physical properties "practically received wisdom" among philosophers of mind. This generalization of the multiple realizability argument also traces back to Fodor (1975 and 1981, Chapter 5). While he targeted explicitly reductionism built on the classical logical empiricist account, he also suggested that his argument applied to more "liberal" versions of reduction then under development. Nonreductive materialists part company with functionalists over the latter's attempt to identify mental kinds with functional kinds. Most of the arguments hinge on issues about individualism in psychology. But a multiple realizability argument has surfaced here. In specifying the nature of mental kinds, many functionalists followed Putnam and Fodor by adopting "Turing machine functionalism": mental kinds are identical to the computational kinds of a suitably programmed universal Turing machine. Putnam (1988) has recently argued that mental kinds are both "compositionally" and "computationally" plastic. The first point is his familiar multiple realizability contention of the mental on the physical. The second contends that the same mental kind can be a property of systems which are not of the same (Turing) computational state. Multiple realizability strikes back at the very theory of mind it initially motivated!

Early Reductionist Replies

David Lewis (reprinted as Chapter 18 in Block 1980) offered the earliest influential reply to Putnam's multiple realizability argument. The inconsistency between the reductionist's thesis and multiple realizability evaporates when we note a tacit relativity to context. A common sense example illustrates Lewis's point. The following three claims appear inconsistent: (1) There is only one winning lottery number. (2) The winning lottery number is 03. (3) The winning lottery number is 61. These three claims seem similarly inconsistent: (1′) (the reductionist thesis) There is only one physical-chemical realization of pain. (2′) The physical-chemical realization of pain is C-fiber firing. (3′) The physical-chemical realization of pain is . . . (something else entirely). ((2′) and (3′) reflect the multiple realizability contention.) But there is no mystery in reconciling (1) -- (3). Append "per week" to (1), "this week" to (2), and "last week" to (3). Similarly, append "per structure-type" to (1′), "in humans" to (2′), and "in mollusks" to (3′). Inconsistency evaporates. Lewis's point is that reductive identities are always specific to a domain.

Many philosophers have elaborated on Lewis's point. Patricia Churchland (1986, Chapter 7), Clifford Hooker (1981), Berent Enç (1983), and other philosophers of science have described historical intertheoretic reductions where a given reduced concept is multiply realized at the reducing level. A common example is the concept of temperature from classical equilibrium thermodynamics. Temperature in a gas is identical to mean molecular kinetic energy. Temperature in a solid, however, is identical to mean maximal molecular kinetic energy, since the molecules of a solid are bound in lattice structures and hence restricted to a range of vibratory motions. Temperature in a plasma is something else entirely, since the molecular constituents of a plasma have been ripped apart. Even a vacuum can have a (blackbody) temperature, though it contains no molecular constituents. Temperature of classical thermodynamics is multiply realized microphysically in a variety of distinct physical states. Yet this is a "textbook" intertheoretic reduction and cross-theory identification. The reduction and identification are

specific to the domain of physical state.

Lewis's insight also underlies Jaegwon Kim's recent appeal to structure-specific "local reductions" (reprinted as Chapters 14 and 16 in Kim 1993). Kim agrees that multiple realizability rules out a general reduction of (structure-independent) psychology to the physical sciences. But it permits (even sanctions) a local reduction to a theory of the physical mechanisms of a given structure-type. (Kim admits that the relevant structure-types here will probably be narrower than biological species.) Local reductions involve "structure-specific bridge laws" where the mental-physical biconditional occurs as the consequent of a conditional whose antecedent denotes a specific structure-type. Conditionals whose antecedents denote different structure types will typically have biconditionals as consequents whose mental term-constituents are coreferential but whose physical term- constituents denote different physical events. Multiple realizability forces this much revision to the bridge laws of classical reductionism. But according to Kim, local reductions are the rule rather than the exception in science generally, and are sufficient for any reasonable scientific or philosophical purpose. Kim's is yet another way to express the tacit specificity to a domain in scientific reductions.

Multiple Realizability Within Structure-Types and Token Systems

The scope of Lewis's strategy and its recent variations is limited, however. They only adequately address the "across structure-types" version of the multiple realizability argument. Recent anti-reductionists have stressed the more radical type. To capture that sense, the context or domain to which a reduction must be relativized is a token system of a structure-type at a time. This much "domain" or "context" specificity seems inconsistent with even a minimally acceptable degree of generality in scientific theorizing. This reply goes back to Ned Block's work in the late 1970s (reprinted as Chapter 22 in Block 1980). Block insisted that the necessary narrowing of psychological kinds renders psychology incapable of capturing whatever generalizations hold across species. Ronald Endicott (1993) gives Block's reply an interesting empirical twist by noting facts about plasticity in the human brain. The capacity for distinct neural structures and processes to subserve a given psychological function owing to trauma, damage, changing task demands, development, and other factors is extensive. A psychology narrowed enough to handle the more radical type of multiple realizability might not be sufficiently general to capture generalizations even within a species whose brains display human-like plasticity.

Against this reply, Kim (1993, Chapter 16) and Bickle (1998, Chapter 4) independently remind us that a guiding methodological principle in contemporary neuroscience assumes some continuity of underlying neural mechanisms. This assumption informs most experimental techniques and paradigms, and theoretical conclusions drawn from experimental data. Continuity is assumed both within and across species. If the radical sense of multiple realizability really obtained, to the extent necessary to circumvent the Lewis-inspired replies to the initial multiple realizability argument, contemporary neuroscientific experimental techniques should bear little fruit. (Why study the macaque visual system to investigate human visual processing, for example, if we can't safely assume some continuity across species? Why

should PET scans reveal common areas of high metabolic activity across and within individual humans, down to less than a centimeter of resolution? Standard neuroscientific experimental procedures and even clinical diagnostic tools would be hopelessly naïve.) These procedures do work, however (and are not hopelessly naïve), and this is evidence that psychological functions might not be so radically multiply realized as recent anti-reductionists pretend. Even neural plasticity is systematic. It has a regular progression following damage to a principal structure; there are underlying neural mechanisms that subserve it. Furthermore, function following damage is often seriously degraded. Persons can still talk, manipulate spatial representations, or move their extremities, but their performance is often qualitatively and quantitatively less than normal. This fact gives rise to tricky questions about individuation of psychological function. Are these alternative neural structures realizing the same psychological function (the same mental kind) as before?

Still, one would like a more direct reply to this more radical type of multiple realizability. Following suggestions by Hooker (1981) and Enc (1983), Bickle (1998, Chapter 4) argues that this feature is common to scientific reductions generally. For example, it obtains in the "textbook" reduction of classical equilibrium thermodynamics to microphysics via statistical mechanics. For any token aggregate of gas molecules, there is an indefinite number of realizations of a given temperature, a given mean molecular kinetic energy. Microphysically, the most fine-grained theoretical specification of a gas is its microcanonical ensemble, in which the momentum and the location (and thus the kinetic energy) of each molecule is specified individually. Indefinitely many distinct microcanonical ensembles of a token volume of gas molecules can yield the same mean molecular kinetic energy. Thus at the lowest level of microphysical description, temperature is vastly multiply realizable in the same token system over time. So even multiple realizability in this more radical sense is not by itself a barrier to reducibility. (Bickle also argues that exactly this relation obtains within "connectionist" theories of representational content.)

Other Replies to Multiple Realizability Arguments

In searching for reductive unity underlying the variety of cognitive systems, Paul Churchland (1982) once suggested descending "below" neurobiology and even biochemistry to the level of nonequilibrium thermodynamics. He insisted that finding reductive unity there was more than a bare logical possibility, because of some parallels between biological processes, whose multiply realized kinds find reductive unity there, and cognitive activity (especially learning). Robert Richardson (1979) once suggested that the Putnam-Fodor challenge resulted from an incomplete understanding of Ernest Nagel's classic account of reduction. Although Nagel's examples involve biconditional cross-theory connections, one-way conditional connections expressing sufficient conditions at the reducing level were all his "principle of derivability" required. (Richardson cites the relevant passages from Nagel's classic exposition.) Multiple realizability only challenges the necessity of (nondisjunctive) reducing conditions, and so is not a challenge to even a projected Nagelian reduction of psychology to the physical sciences.

Besides his appeal to species-specific bridge laws and local reducibility, Kim (1993, Chapter 14) has recently offered two additional replies to the multiple realizability argument. His "projectability" reply starts from the familiar fact that the kind "jade" fragments into jadeite and nephrite. This renders jade

incapable of passing the projectability test for nomicness because of its genuinely disjunctive nature. Multiple realizability of psychological kinds yields the same consequence. Instead of rendering psychology an autonomous special science, multiple realizability implies that there is no structure-independent scientific psychology. There are only "local" scientific psychologies reducible to the theory of the underlying physical mechanisms of the structure-type in question. Closely related is his "causal powers" reply. Scientific kinds are individuated by their causal powers, and the causal powers of each instance of some realized kind are identical to those of its realizer. From these principles it follows that instances of a mental kind with different physical realizations are distinct kinds. Thus (structure-independent) mental kinds are not causal kinds, and hence are disqualified as proper scientific kinds. Multiple realizability yields the failure of structure-independent mental kinds to meet the standards of scientific kinds. (Terence Horgan 1996 has mounted some interesting rejoinders to these related arguments.)

With regard to Pylyshyn's (1984) attack on reductionist methodology, Patricia Churchland (1986, Chapter 9) suggests that lower level sciences themselves can construct functional theories. This inserts a new level of theory between that of the structure of the lower level kinds and that of purely functional kinds: between, for example, the physiology of individual neurons and cognitive psychology. We might find a common neurofunctional property for a given type of psychological state. And if the scope of the macro-theory doesn't extend beyond that of its microfunctional counterpart, then reduction will be achieved despite vast multiple realizability at the microstructural level. Neurocomputational approaches that have blossomed recently give empirical credence to Churchland's suggestion. Bickle (1998, Chapters 3 and 4) has tried to explain how such a result is sufficient for reduction by building some suggestions from Hooker (1981, Part III) about "cross categorial" and "token-to-token" reductions into a general model of the intertheoretic reduction relation. The cross-classifications implied by multiple realizability might require that a special kind of reduction relation obtain between psychology and the physical sciences. But this will be reduction enough, with plenty of scientific precedent.

Finally, notice that all reductionist responses discussed so far refrain from attacking the multiple realizability contention itself. Even this has been attacked. Nick Zangwill (1992) insists that multiple realizability across biological species has not been proven. The multiple realizability contention assumes a type-identity of mental kinds across species. This assumption is problematic, given that the obvious sensory and motor differences alone will yield different cause-and-effect patterns at all but the grossest level of description. We are back to tricky issues about how psychology individuates types. It is interesting to note in closing that nobody has developed the argument that the multiple realizability contention rests precariously on "folk" intuitions about mental type-individuation.

Physicalism

Physicalism is the thesis that everything is physical, or as contemporary philosophers sometimes put it, that everything supervenes on the physical. The thesis is usually intended as a metaphysical thesis, parallel to the ancient Greek philosopher Thales's thesis that everything is water, or the idealism of the 18th Century philosopher Berkeley, that everything is mental. The general idea is that the nature of the actual world (i.e. the universe and everything in it) conforms to a certain condition, the condition of being physical. Of course, physicalists don't deny that the world might contain many items that at first glance don't *seem* physical -- items of a biological, or psychological, or moral, or social nature. But they insist nevertheless that at the end of the day such items are wholly physical.

Physicalism is sometimes known as materialism. Historically, materialists held that everything was matter -- where matter was conceived as "an inert, senseless substance, in which extension, figure, and motion do actually subsist" (Berkeley, *Principles of Human Knowledge*, par. 9). The reason for speaking of physicalism rather than materialism is to abstract away from this historical notion, which is usually thought of as too restrictive -- for example, forces such as gravity are physical but it is not clear that they are material in the traditional sense (Dijksterhuis 1961, Yolton 1983). It is also to emphasize a connection to physics and the physical sciences. Indeed, physicalism is unusual among metaphysical doctrines in being associated historically with a commitment both to the sciences and to a particular branch of science, namely physics.

---

1. A Framework for Discussion

In approaching the topic of physicalism, one may distinguish what I will call *the interpretation question* from *the truth question*. The interpretation question asks:

- What does it *mean* to say that everything is physical?

The truth question asks:

- Is it *true* to say that everything is physical?

There is obviously a sense in which the second question here presupposes an answer to the first -- you need to know what a statement means before you can ask whether it's true -- and I will begin with the interpretation question. Nevertheless, the issues here turn out to be somewhat technical, and those new to the topic might like to read only the first section of my discussion of the interpretation question, which is: Supervenience Physicalism: Introductory, and then turn directly to the truth question which begins at The Case Against Physicalism I: Qualia and Consciousness.

The interpretation question itself divides into two sub-questions, which I will call *the completeness question* and *the condition question*. The completeness question asks:

- What does it mean to say that *everything* is physical?

In other words, the completeness question holds fixed the issue of what it means for something to satisfy the condition of being physical, and asks instead what it means for *everything* to satisfy that condition. Notice that a parallel question could be asked of Thales: assuming we know what condition you have to satisfy to be water, what does it mean to say that everything satisfies that condition?

The condition question asks:

- What does it mean to say that everything is *physical*?

In other words, the condition question holds fixed the issue of what it means for everything to satisfy some condition or other, and asks instead what *is* the condition, being physical, that everything satisfies. Notice again that a parallel question could be asked of Thales: assuming we know what it is for everything to satisfy some condition or other, what is the condition, being water, that according to Thales, everything satisfies? In discussing the interpretation question, I will turn first to the completeness question, and then consider the condition question.

2. Supervenience Physicalism: Introductory

In attempting to answer the completeness question, it has become customary since Davidson 1970 to look to the notion of supervenience. (The notion of supervenience is historically associated with meta-ethics, but it has received extensive discussion in the general metaphysics and logic literature. For a survey, see Kim 1993.)

The idea of supervenience might be introduced via an example due to David Lewis of a dot-matrix picture:

> A dot-matrix picture has global properties -- it is symmetrical, it is cluttered, and whatnot -- and yet all there is to the picture is dots and non-dots at each point of the matrix. The global properties are nothing but patterns in the dots. They supervene: no two pictures could differ in their global properties without differing, somewhere, in whether there is or there isn't a dot (1986, p. 14).

Lewis's example gives us one way to introduce the basic of idea of physicalism. The basic idea is that the physical features of the world are like the dots in the picture, and the psychological or biological or social features of the world are like the global properties of the picture. Just as the global features of the picture are nothing but a pattern in the dots, so too the psychological, the biological and the social features of the world are nothing but a pattern in the physical features of the world. To use the language of supervenience, just as the global features of the picture supervene on the dots, so too everything supervenes on the physical, if physicalism is true.

It is desirable to have a more explicit statement of physicalism, and here too Lewis's example gives us direction. Lewis says that, in the case of the picture, supervenience means that "no two pictures can be identical in the arrangement of dots but different in their global properties". Similarly, one might say that, in the case of physicalism, no two possible worlds can be identical in their physical properties but differ, somewhere, in their mental, social or biological properties. To put this slightly differently, we might say that if physicalism is true at our world, then no *other* world can be physically identical to it without being identical to it in all respects. This suggests the following account of what physicalism is:

> (1) Physicalism is true at a possible world *w* iff any world which is a physical duplicate of *w* is a duplicate of *w simpliciter*.

If physicalism is construed along the lines suggested in (1), then we have an answer to the completeness question. The completeness question asks: what does it mean to say that *everything* is physical. According to (1), what this means is that if physicalism is true, there is no possible world which is identical to the actual world in every physical respect but which is not identical to it in a biological or social or psychological respect. It will be useful to have a name for physicalism so defined, so let us call it *supervenience physicalism*.

3. Supervenience Physicalism: Further Issues

Supervenience physicalism is relatively simple and clear, but when construed as a formulation of physicalism, it faces three initial problems: (a) the epiphenomenal ectoplasm problem; (b) the lone ammonium molecule problem; (c) the modal status problem; and (d) the necessary beings problem.

The epiphenomenal ectoplasm problem

(Cf. Horgan 1983, Lewis 1983.) Imagine a possible world *W* that is exactly like our world in respect of the distribution of physical and mental properties, but for one difference: it contains some pure experience which does not interact causally with anything else in the world -- *epiphenomenal ectoplasm*, to give it a name. The problem this possibility presents for (1) is that, if (1) provides the correct definition of physicalism, and if physicalism is true at the actual world, then there is *no* possible world of the kind we just described, i.e., *W* does not exist. The reason is that *W* is by assumption a physical duplicate of our world; but then, if physicalism is true at our world, *W* should be a duplicate simpliciter of our world. But *W* is patently not a duplicate of our world: it contains some epiphenomenal ectoplasm that our world lacks. On the other hand, it seems quite wrong to say that *W* is an impossibility -- at any rate, physicalism should not *entail* that it is impossible.

In order to solve the epiphenomenal ectoplasm problem, we need to adjust (1) so that it does not have the truth of physicalism ruling out *W* as a possible world. While there are a number of different proposals about how to do this, the simplest is due to Frank Jackson (cf. Jackson 1993. For earlier proposals and further discussion, see Horgan 1983 and Lewis 1983.) He proposes replacing (1) with:

> (2) Physicalism is true at a possible world *w* iff any world which is a minimal physical duplicate of *w* is a duplicate of *w simpliciter*

By ‘minimal physical duplicate’, Jackson means a possible world that is identical in all physical respects to the actual world, but which does not contain anything else; in particular, it does not contain any epiphenomenal ectoplasm. Unlike (1), (2) does not have physicalism ruling out *W*, and so (2) is preferable to (1), as a statement of physicalism, and it is (2) with which we shall work in this entry.

The lone ammonium molecule problem

(Cf. Kim 1993.) Imagine a possible world *W** that is physically exactly like our world except in one trivial respect: it has one extra ammonium molecule located, say, on Saturn's rings. It is natural to suppose that at *W**, the distribution of mental properties is exactly as it is in the actual world -- the presence of an extra molecule does not make that much of a difference. On the other hand, for all (2) says, such a world might be *radically different* in terms of the distribution of mental properties. Since (2) only refers to worlds that are exact minimal physical duplicates of our world, it is silent on worlds that are different *even in minute details*, and hence is silent on *W**. It thus leaves open the possibility that, in *W**, everything has mental properties, or nothing has or the only things that have mental properties are Saturn's rings! But that seems absurd: while *W** is clearly not a physical duplicate of our world, for it contains an extra molecule, the distribution of mental properties in *W** would nevertheless match that of the actual world.

Once again there are a number of different responses to this problem in the literature (cf. Kim 1993). But perhaps the simplest response is that the problem conflates two issues that are better kept apart: the question of what physicalism itself tells us about *W**, and the question of what our general knowledge tells us about *W**. It is true that physicalism itself does not tell us anything about the distribution of mental properties at *W**. Nevertheless, we know independently what the distribution is -- we know independently that the presence or absence of molecules on Saturn doesn't affect things like who has mental properties here on Earth. But why should one assume that this last piece of knowledge should be a consequence of physicalism? To put the point slightly differently, imagine that we discover that who has mental properties on Earth *is* in part a function of the behavior of molecules on Saturn. That would of course tell us that we are deeply wrong in our assumptions about how the world works. But it would not tell us that we are deeply wrong about physicalism. (For further discussion of this point, see Paull and Sider 1992, and Stalnaker 1996.)

The modal status problem

Some philosophers (e.g. Davidson 1970) have thought of physicalism as a conceptual or necessary truth, if it is true at all. But most have thought of it as contingent, a truth about our world which might have been otherwise. The statement of physicalism encoded in (2) allows a way in which this might be so. (2) tells us that physicalism is true at a world just in case the world in question conforms to certain conditions. But it leaves it open whether or not the actual world conforms to those conditions *as a matter of fact*. Perhaps it is *not* true of our world that a physical duplicate of it would be a psychological duplicate. If so, physicalism would not be true at our world.

But for some it is puzzling that physicalism is stated using modal notions (i.e. notions such as possible worlds) and nonetheless is contingent. To see the problem, notice first that, supervenience physicalism tells us that the minimal physical truths of the world entail *all* the truths; hence

> (3) The minimal physical truths entail all the truths.

Now suppose that *S* is a statement which specifies the minimal physical nature of the actual world and *S**

is a statement which specifies the total nature of the world. (It might be that neither *S* nor *S** are expressible in languages we can understand, but let us set this aside.) If supervenience physicalism is true, it will then be true that:

> (4) *S* entails *S**

On the other hand, (4) is clearly a necessary truth. However, if (4) is a necessary truth, how can *physicalism* be contingent? After all, (4) seems equivalent to physicalism. But if the two are equivalent, how can one be necessary and the other contingent?

But the response to this problem is straightforward. (4) is necessary, but it is *not* equivalent to physicalism. Rather, (4) *follows* from physicalism given various contingent assumptions, in particular the assumptions that *S* and *S are* the statements we say they are -- it is contingent fact, for example that *S** summarizes the total nature of the world. On other hand, (3) *is* equivalent to physicalism but it is *not* necessary. (It is important to bear in mind here that not all entailment claims are necessary. Consider 'my aunt's favorite statement entails my uncle's favorite' -- that statement is contingent even though it is most naturally thought of as an entailment claim.)

The necessary beings problem

(Cf. Jackson 1998) Imagine a necessary being -- that is, a being which exists in all possible worlds -- which is essentially nonphysical. (Some theists believe that God provides an example of such a being.) If such a non-physical being exists, it is an natural to suppose that physicalism is false. But if physicalism is defined according to (2), the existence of such a being is compatible with physicalism. For consider: if the actual world is wholly physical, apart from the necessary non-physical being, any minimal physical duplicate of the actual world is a duplicate simpliciter. Since the non-physical being exists in all possible worlds, it exists at all worlds which are minimal physical duplicates of the actual world. So we seem to face a problem: the existence of the non-physical necessary being entails that physicalism is false, but the definition of physicalism permits it to be true in this case.

This problem is not so easily answered as the previous three. Lying behind the problem is a deeper issue about the correct interpretation of necessity and possibility -- the modal notions one uses to formulate supervenience. On one way of interpreting these notions, the existence of a necessary being of this sort is incoherent. A reason is that it would violate David Hume's famous dictum that there are no necessary connections between distinct existences -- the being is distinct from the physical world and yet is necessitated by it. On another way of interpreting these notions, however, there is nothing incoherent in the idea of such a being. The correct way to think about modal notions, however, is a topic that is well beyond the scope of our discussion here. The problem seems to be that the supervenience definition of physicalism in effect presupposes something like Hume's dictum, in that it uses failure of necessitation as a test for distinctness. But this means that someone who denies the dictum will have to find an alternative way of formulating physicalism.

4. Minimal Physicalism and Philosophy of Mind

We saw earlier that physicalism is intended as a very general claim about the nature of the world. Nevertheless, by far the most discussion of physicalism in the literature has been in the philosophy of mind The reason for this is that it is in philosophy of mind that we find the most plausible and compelling arguments that physicalism is false. Indeed, as we will see later on, arguments about qualia and consciousness are usually formulated as arguments for the conclusion that physicalism is false. Thus, much of philosophy of mind is devoted to a discussion of physicalism. Most contemporary philosophers are physicalists. But some, dualists, deny physicalism and thus deny that consciousness supervenes on the physical.

While the issue of physicalism is central to philosophy of mind, however, it is important also to be aware that supervenience physicalism is neutral on a good many of the questions that are pursued in philosophy of mind, and pursued elsewhere for that matter. If you read over the philosophy of mind literature, you will often find people debating a number of different issues: whether there *are* mental states at all; what *sort* of thing mental states are; to what extent mental states are environmentally determined. Given the multifariousness of mental states, it is quite likely that the correct position will be some kind of combination of these positions. But this is a question of further inquiry that is irrelevant to physicalism itself. So physicalism itself leaves many debates in the philosophy of mind unanswered.

This point is sometimes expressed by saying that *supervenience physicalism is minimal physicalism* (Lewis 1983): it is intended to capture the minimal or core commitment of physicalism. Physicalists may differ from one another in many ways, but all of them must at least hold supervenience physicalism. (Notice that the idea that (2) captures the minimal commitment of physicalism is a distinct idea from that of a minimal physical duplicate which it uses to capture minimal physicalism.)

Two issues here require further comment. First, in some discussions in philosophy of mind, the term ‘physicalism’ is used to refer to the identity theory, the idea that mental states or properties are neurological states or properties (Block 1980). In this use of the term, one can reject physicalism by rejecting the identity theory -- so by that standard a behaviorist or functionalist in philosophy of mind would not count as a physicalist. Obviously, this is a much more restricted use of the term than is being employed here.

Second, one might think that supervenience physicalism is inconsistent with eliminativism, the claim that psychological states do not exist, for the following reason. Suppose psychological states supervene on physical states. Doesn't that mean, contrary to eliminativism, that there must *be* some psychological states? The answer to this question is ‘no.’ For consider: the telephone on my desk has no psychological states whatsoever. Nevertheless it is still true (though, admittedly, a little odd) to say that a telephone which is identical to my telephone in all physical respects will be identical to it in all psychological respects. In the sense intended, therefore, one thing can psychologically identical to another even when neither *has* any psychological states.

5. Token and Type Physicalism

To what extent does supervenience physicalism capture minimal physicalism, the core commitment of all physicalists? In order to answer this question it is worth comparing and contrasting supervenience physicalism with two alternative statements of physicalism that one finds in the literature: token and type physicalism.

Token physicalism is the view that every particular thing in the world is a physical particular. Here is one formulation of this idea:

> **Token physicalism**:
> For every actual particular (object, event or process) *x*, there is some physical particular *y* such that *x* = *y*.

Supervenience physicalism neither implies nor is implied by token physicalism. To see that token physicalism does not imply supervenience physicalism, one need only note that the former is consistent with a version of dualism, namely property dualism. The mere fact that every particular has a physical property does not rule out the possibility that some particulars also have non-supervenient mental properties, i.e. mental properties that are only contingently related to the physical. But supervenience physicalism *does* rule out this possibility. Since token physicalism does not rule out property dualism but supervenience physicalism does, the first does not imply the second.

To see that supervenience physicalism does not imply token physicalism is more difficult. The crucial point is that token physicalism requires that for every psychological or social particular, there is some physical particular with which it is identical. But this is by no means obviously true. Consider the United States Court of Appeals for the Seventh Circuit. This might thought of as a social or legal object. But then, according to token physicalism, there must be some physical object for it to be identical with. But there might be no physical object (in any natural sense of the term) which is identical to the Court of Appeals for the Seventh Circuit. On the other hand, supervenience physicalism imposes no such requirement, and so supervenience physicalism does not imply token physicalism (For the classic presentation of this point, see Haugeland 1983).

The point that supervenience physicalism is logically distinct from token physicalism is an important one. One thing it shows is that token physicalism (since it is consistent with property dualism) does not capture minimal physicalism, and so the distinction between token physicalism and supervenience physicalism is no objection to the latter. But the difference between the two theses also raises a different question. Given that token physicalism does not capture the minimal commitment of physicalism, why has token physicalism been the subject of such discussion? One reason is that token physicalism provides one version of the idea that upper level scientific claims requires physical mechanisms. Supervenience physicalism does not on its own entail this. But token physicalism is often seen as a way to ensure this requirement. (For the classic presentation of this point, see Fodor 1974; see also Papineau 1996)

Having considered token physicalism, we can now turn to type physicalism. Type physicalism is a generalization and extension of the identity theory, which we considered above. It holds that that every property (or at least every property that is or could be instantiated in the actual world) is identical with some physical property. Here is a statement of this sort of idea:

> **Type physicalism**:
> For every actually instantiated mental property *F*, there is some physical property *G* such that *F*=*G*.

Unlike token physicalism, type physicalism certainly *does* entail supervenience physicalism: if every property instantiated in the actual world is identical with some physical property, then a world identical to our world in physical respects will of course be identical to it in all respects.

Nevertheless the reverse entailment does not hold. Supervenience physicalism, as we have been understanding it, is a contingent thesis that is consistent with the possibility (if not the actuality) of disembodiment. But type physicalism as defined here is inconsistent with this possibility. To that extent, supervenience physicalism does not entail type physicalism.

Earlier we noted that philosophers such as Davidson have thought that physicalism is a necessary truth. Even on that assumption, however, it is still not completely obvious that supervenience physicalism entails type physicalism. The reason for this has to do with questions concerning the logical (or Boolean) closure of the set of physical properties -- if *P*, *Q* and *R* are physical properties, which of the various logical permutations of *P*, *Q* and *R* are likewise physical properties? On some assumptions concerning closure and supervenience, supervenience physicalism (construed as a necessary truth) entails type physicalism; on other assumptions, it doesn't. But the problem is that the assumptions themselves are difficult to interpret and evaluate, and so the issue remains a difficult one. It is not necessary for our purposes to settle the question concerning closure here. (For further discussion of these issues see Kim 1993, Bacon 1990, Van Cleve 1990, Stalnaker 1996.)

6. Reductive and Non-Reductive Physicalism

Before the development and study of the notion of supervenience, physicalism was often stated as a reductionist thesis. It will therefore be useful to contrast the supervenience formulation of physicalism with various reductionist proposals, and also turn to a question that has received a lot of attention in the literature, viz., whether a physicalist must be a reductionist.

The main problem in assessing whether a physicalist must be a reductionist is that there are various non-equivalent versions of reductionism.

One idea is tied to the notion of conceptual or reductive analysis. When philosophers attempt to provide an analysis of some concept or notion, they usually try to provide a reductive analysis of the notion in question, i.e. to analyze it in other terms. Applied to the philosophy of mind, this notion might be thought

of entailing the idea that every mental concept or notion is analyzed in terms of a physical concept or notion. A formulation of this idea is (5):

> (5) Reductionism is true iff for each mental predicate *F*, there is a physical predicate *G* such that a sentence of the form ‘ *x* is *F* iff *x* is *G*’ is analytically true.

While one occasionally finds in the literature the suggestion that physicalists are committed to (5) in fact, no physicalist since before Smart (1959) has (unqualifiedly) held anything like (5). Adapting Ryle (1949), Smart supposed that in addition to physical expressions there is a class of expressions which are topic-neutral, i.e. expressions which were neither mental nor physical but when conjoined with any theory would greatly increase the expressive power of the theory. Smart suggested that one might analyze mental expressions in topic-neutral (but not physical) terms, which in effect means that a physicalist could reject (5). It is fair to say that this move is one of the central innovations of philosophy of mind, a move to a large extent endorsed and developed by functionalists and cognitive scientists.

A different notion of reduction derives from the attempts of philosophers of science to explain intertheoretic reduction. The classic formulation of this notion was given by Ernest Nagel (1961). Nagel said that one theory was reduced to another if you could logically derive the first from the second together with what he called bridge laws, i.e., laws connecting the predicates of the reduced theory (the theory to be reduced) with the predicates of the reducing theory (the theory to which one is reducing). Here is a formulation of this idea, where the theories in question are psychology and neuroscience:

> (6) Reductionism is true iff for each mental predicate *F* there is a neurological predicate *G* such that a sentence of the form ‘*x* is *F* iff *x* is *G*’ expresses a bridge law.

Once again, however, there is no reason at all why physicalists need to accept that reductionism is true in the sense of (6). Indeed, many philosophers have argued that there are very strong empirical reasons to deny that anything like (6) is going to be the case. The reason is this. Many different neurological processes (whether in our own species or a different one) could underlie the same psychological process -- indeed, given science fiction, even non-neurological processes might underlie the same psychological process. But if multiple realizability -- as this sort of idea is called -- is true, then (6) seems to be false. (Fodor 1974, but for recent alternative views, see Kim 1993).

A third notion of reductionism is more metaphysical in focus than either the conceptual or theoretical ideas reviewed so far. According to this notion, reductionism means that the properties expressed by the predicates of (say) a psychological theory are identical to the properties expressed by the predicates of (say) a neurological theory -- in other words, this version of reductionism is in essence a version of type physicalism or the identity theory. However, as we have seen, if physicalists are committed only to supervenience physicalism, they are not committed to type physicalism. Hence a physicalist need not be a reductionist in this metaphysical sense.

A final notion of reductionism that needs to be distinguished from the previous three concerns whether mental statements follow *a priori* from non-mental statements. Here is a statement of this sort of idea,

> (7) Reductionism is true iff for each mental predicate *F* there is non-mental predicate *G* such that a sentence of the form ‘ if *x* is *F* then *x* is *G*’ is *a priori*.

What (7) says is that if reductionism is true, *a priori* knowledge alone, plus knowledge of the physical truths will allow one to know the mental truths. This question is in fact a highly vexed one in contemporary philosophy. However, this question is usually debated in the context of another, viz., the question of *a posteriori* and *a priori* physicalism. It is to that question, therefore, to which we will now turn.

7. *A Priori* and *A Posteriori* Physicalism

We saw earlier that if physicalism is true then (4) is true, where ‘*S*’ is a sentence that reports the entire physical nature of the world and ‘*S**’ is a sentence that reports the entire nature of the world:

> (4) *S* entails *S**

Another way to say this is to say that if physicalism is true, then the following conditional is necessarily true:

> (8) If *S* then *S**

Indeed, this is a general feature of physicalism: if it is true then there will always be a necessary truth of the form of (8).

Now, if (8) is necessary the question arises whether it is *a priori*, i.e. knowable independent of empirical experience, or whether it is *a posteriori*, i.e. knowable but not independently of empirical experience. Traditionally, every statement that was necessary was assumed to be *a priori*. However, since Kripke's classic work *Naming and Necessity* (1980), philosophers have become used to the idea that there are truths which are both necessary and *a posteriori*. Accordingly many recent philosophers have defended a *posteriori physicalism*: the claim that statements such as (8) are necessary and *a posteriori* (cf. Loar 1997). Moreover, they have used this point to try to disarm many objections to physicalism, including those concerning qualia and intentionality that we will consider in a moment. Indeed, as we have just noted, some philosophers have suggested that the necessary *a posteriori* provides the proper interpretation of non-reductive physicalism.

The appeal to the necessary *a posteriori* is on the surface an attractive one, but it is also controversial. One problem arises from the fact that Kripke's idea that there are necessary and *a posteriori* truths can be interpreted in two rather different ways. On the first interpretation -- I will call it the derivation view -- while there are necessary *a posteriori* truths, these truths can be derived *a priori* from truths which are *a posteriori* and contingent. On the second interpretation -- I will call it the non-derivation view -- there are

non-derived necessary *a posteriori* truths, i.e. necessary truths which are not derived from any contingent truths (or any *a priori* truths for that matter). The problem is that when one combines the derivation view with the claim that (8) is necessary and *a posteriori*, one encounters a contradiction. If the derivation view is correct, then there is some contingent and *a posteriori* statement *S#* that logically entails (8). However, if *S#* logically entails (8) then (since ‘If *C*, then if *A* then *B*’ is equivalent to ‘If *C* & *A*, then *B*’) we can infer that the following is both necessary and *a priori*:

> (9) If *S* & *S#* then *S**.

One the other hand, if physicalism is true, and *S* summarizes the total nature of the world it seems reasonable to suppose that *S# was already implicitly included in S*. In other words it seems reasonable to suppose that (9) is simply an expansion of (8). But if (9) is just an expansion of (8), then if (9) is *a priori*, (8) must also be *a priori*. But that means our initial assumption is false: (8) is not a necessary *a posteriori* truth after all (Jackson 1998).

How might an *a posteriori* physicalist respond to this objection? The obvious response is to reject the derivation view of the necessary *a posteriori* in favor of the non-derivation view. But this is just to say that if one wants to defend *a posteriori* physicalism, one will have to defend the non-derivation view of the necessary *a posteriori*. However, the problem here is that the non-derivation view is very controversial. Indeed, the question of which interpretation of Kripke's work is the right one, is one of the most vexed in contemporary analytic philosophy. So it is not something that we can hope to solve here. (For discussion, see Byrne 1999, Chalmers 1996 1999, Jackson 1998, Loar 1997, 1999, Lewis 1994, Yablo 1999.)

8. Physicalism and Emergentism

A further issue needs to be mentioned in connection with the distinctions between non-reductive and reductive physicalism, and with *a posteriori* and *a priori* physicalism. Kim and others have suggested that non-reductive physicalism is a form of *emergentism*, the view that supervenience provides a way to interpret the relation between the psychological and the physical in such a way that the psychological is *genuinely novel.* (Emergentism was influential in the first forty years of the twentieth century, but it is not unfair to say that similar positions are defended by many contemporary philosophers. For the historical background, see MacLaughlin 1992.)

Now it is difficult to evaluate emergentism because it is unclear what genuine novelty is supposed to be. On one interpretation, what the emergentists meant by ‘genuine novelty’ was non-predictability in principle, i.e. the idea that no matter how much physical information you had about a creature you could not predict on that basis alone what experiences, if any, they might have. On this interpretation, emergentism seems very similar to *a posteriori* physicalism (Byrne 1993). On a different interpretation, what the emergentists meant by ‘genuine novelty’ was the idea that there was only a contingent connection between psychological states and physical state, a connection perhaps mediated by contingent psycho-physical laws. On this interpretation, however, emergentism seems simply to be a denial of

physicalism as we have defined it here.

There is, however, a third interpretation of ‘genuine novelty’ which requires separate treatment. On this interpretation, the idea of genuine novelty is the idea of a layered world: a world that has genuine levels (i.e. levels distinct from one another), and that each of these levels are necessarily connected to others. So interpreted, emergentism is the view that our world is such a layered world.

Now, this version of emergentism does present a problem for our account. To see this, imagine that you begin with a classical form of dualism, and then discover that the laws which related the mental level to the physical level are metaphysically necessary, rather than contingent. In that situation, it is not clear that you have discovered that dualism is false. So emergentism seems to be consistent with dualism. On the other hand, emergentism seems also to be consistent with supervenience physicalism, since according to emergentism, any world physically identical to the actual world will be identical to it in all respects. However -- and here is the final point -- we have been assuming all along that supervenience physicalism is inconsistent with dualism. In short, the problem is this: (a) supervenience physicalism is consistent with emergentism; (b) emergentism is consistent with dualism; but (c) supervenience physicalism is *in*consistent with dualism.

How are we to respond to this problem? I think the best thing to say is that emergentism and physicalism are inconsistent, and hence that (a) is false. However, the inconsistency does not have its source in the formal notion of supervenience. Instead it has its source in the interpretation that both views assign to that notion. The emergentist is obviously being guided by the metaphor of layers, and interprets supervenience in that light. However, while one sometimes uses the metaphor of layers to describe the world as portrayed by supervenience physicalism, it would be more apt to say -- as Lewis says in the example of the dot-matrix picture that we considered above -- that that doctrine presents the psychological, the biological and so on as *patterns in* the physical, rather than *layers on top of* the physical. So the picture implicit in emergentism is that of *a layered world*, whereas the picture implicit in supervenience physicalism is that of *a patterned world*. Since these pictures are inconsistent, (a) is false.

Even if emergentism is distinct from supervenience physicalism, however, it remains a controversial issue whether the emergentist picture can be made fully coherent (Stalnaker 1996). One sort of argument against it is that it seems to violate Hume's dictum that there are no necessary connections between distinct existences: according to emergentism, the levels of the world are wholly distinct from each other, and yet are necessarily connected (Jackson 1993) However, as we saw in our discussion above of the necessary beings problem, the proper interpretation of Hume's dictum is itself a matter of controversy, so emergentism remains controversial.

9. Understanding ‘Physical’: Introductory

Earlier we distinguished two interpretative questions with respect to physicalism, the completeness question and the condition question. So far we have been concerned with the completeness question. I turn now to the condition question, the question of what it is for something (an object, an event, a process,

a property) to be a physical.

The condition question that has received less attention in the literature than the questions we have been studying so far. But it is just as important. Without any understanding of what the physical is, we can have no serious understanding of what physicalism is. After all, if we say that, no two possible worlds can be minimal physical duplicates without being duplicates simpliciter, we don't know what we've said unless we understand what it would take to be a minimal physical duplicate, as opposed (say) to a chemical duplicate or a financial duplicate. (The point here is a quite general one: if Thales says that everything is water, or Up-to-Date-Thales says everything supervenes on water, we don't understand what he says unless he says something about what water is. The physicalist is in the same position.)

So what is the answer to the condition question? If we concentrate for simplicity on the notion of a physical property, we can discern two kinds of answers to this question in the literature. The first ties the notion of a physical property to a notion of a physical theory, for this reason we can call it the theory based conception of a physical property:

> **The theory-based conception**:
> A property is physical iff it either is the sort of property that physical theory tells us about or else is a property which metaphysically (or logically) supervenes on the sort of property that physical theory tells us about.

According to the theory-based conception, for example, if physical theory tells us about the property of having mass, then having mass is a physical property. Similarly, if physical theory tells us about the property of being a rock -- or, what is perhaps more likely, if the property of being a rock supervenes on properties which physical theory tell us about -- then it too is a physical property. (The theory-based conception bears some relation to the notion of physical1 discussed in Feigl 1965; more explicit defense is found in Smart 1978, Lewis 1994, Braddon-Mitchell and Jackson 1996, and Chalmers 1996.)

The second kind of answer ties the notion of a physical property to the notion of a physical object, for this reason we can call it the object-based conception of a physical property:

> **The object-based conception**:
> A property is physical iff: it either is the sort of property required by a complete account of the intrinsic nature of paradigmatic physical objects and their constituents or else is a property which metaphysically (or logically) supervenes on the sort of property required by a complete account of the intrinsic nature of paradigmatic physical objects and their constituents.

According to the object-based conception, for example if rocks, trees, planets and so on are paradigmatic physical objects, then the property of being a rock, tree or planet is a physical property. Similarly, if the property of having mass is required in a complete account of the intrinsic nature of physical objects and their constituents, then having mass is a physical property. (The best examples of philosophers who operate with the object-conception of the physical are Meehl and Sellars 1956 and Feigl 1965; more

recent defense is to be found in Jackson 1998.)

It is important to note that both conceptions of the physical remain silent on the question of whether topic-neutral or functional properties should be treated as physical or not. To borrow a phrase from Jackson (1998), however, it seems best to treat these properties as onlooker properties: given any set of physical properties, one might add onlooker properties without compromising the integrity of the set. But onlooker properties should not be treated as being physical by definition.

10. Understanding ‘Physical’: Further Issues

Along with the concepts of space, time, causality, value, meaning, truth and existence, the concept of the physical is one of the central concepts of human thought. So it should not be surprising that any attempt to come to grips with what a physical property will be controversial. The theory and object conceptions are no different: each has provoked a number of different criticisms. In this section, I will review some main ones.

Circularity

One might object that both conceptions are inadequate because they are circular, i.e., both appeal to the notion of something physical (a theory or an object) to characterize a physical property. But how can you legitimately explain the notion of one sort of physical thing by appealing to another?

However, the response to this is that circularity is only a problem if the conceptions are interpreted as providing a reductive analysis of the notion of the physical. But there is no reason why they should be interpreted as attempting to provide a reductive analysis. After all, we have many concepts that we understand without knowing how to analyze (cf. Lewis 1970). So there seems no reason to suppose that either the theory or object conception is providing anything else a way of understanding the notion of the physical.

The point here is an important one in the context of the condition question. Earlier we said that the condition question was perfectly legitimate because it is legitimate to ask what the condition of being physical is that, according to physicalism, everything has. But this legitimate question should not be interpreted as the demand for a reductive analysis of the notion of the physical. Consider Thales again: it is right to ask Thales what he means by ‘water’ -- and in so doing demand an understanding of the notion of water -- but it is wrong to demand of him a conceptual analysis of water.

Hempel's dilemma

One might object that any formulation of physicalism which utilizes the theory-based conception will be either trivial or false. Carl Hempel (cf. Hempel 1970, see also Crane and Mellor 1990) provided a classic formulation of this problem: if physicalism is defined via reference to contemporary physics, then it is

false -- after all, who thinks that contemporary physics is complete? -- but if physicalism is defined via reference to a future or ideal physics, then it is trivial -- after all, who can predict what a future physics contains? Perhaps, for example, it contains even mental items. The conclusion of the dilemma is that one has no clear concept of a physical property, no concept that is clear enough to do the job that philosophers of mind want the physical to play.

One response to this objection is to take its first horn, and insist that, at least in certain respects contemporary physics really is complete or else that it is rational to believe that it is (cf. Smart 1978, Lewis 1994 and Melnyk 1997). But while there is something right about this, there is also something wrong about it. What is right about it is that there is a sense in which it is rational to believe that physics is complete. After all, isn't it rational to believe that the most current science is true? But even so -- and here is what is wrong about the suggestion -- it is still mistaken to *define* physicalism with respect to the physics that happens to be true in this world. The reason is that whether a physical theory is true or not is a function of the contingent facts; but whether a property is physical or not is a not function of the contingent facts. For example, consider medieval impetus physics. Medieval impetus physics is false (though of course it might not have been) and thus it is irrational to suppose it true. Nevertheless, the property of having impetus -- the central property that objects have according to impetus physics -- is a physical property, and a counterfactual world completely described by impetus physics would be a world in which physicalism is true. But it is hard to see how any of this could be right if physicalism were defined by reference to the physics that we have now or by the physics that happens to be true in our world.

A different response to Hempel's dilemma is that what it shows, if it shows anything, is that a particular proposal about how to define a physical property -- namely, via reference to physics at a particular stage of its development -- is mistaken. But from this one can hardly conclude that we have no clear understanding of the concept at all. As we have seen, we have many concepts that we don't know how to analyze. So the mere fact -- if indeed it is a fact -- that a certain style of analysis of the notion of the physical fails does not mean that there is no notion of the physical at all, still less that we don't understand the notion.

One might object that, while these remarks are perfectly true, they nevertheless don't speak to something that is right about Hempel's dilemma, namely that for the theory-conception to be complete one needs to say a little more about what physical theory is. Here, however, we can appeal to the fact that we have a number of paradigms of what a physical theory is: common sense physical theory, medieval impetus physics, Cartesian contact mechanics, Newtonian physics, and modern quantum physics. While it seems unlikely that there is any *one* factor that unifies this class of theories, it does not seem unreasonable that there is a cluster of factors -- a common or overlapping set of theoretical constructs, for example, or a shared methodology. In short, we might say that the notion of a physical theory is a Wittgensteinian family resemblance concept, and this should be enough to answer the question of how to understand physical theory.

The panpsychism problem

Hempel's dilemma against the theory-conception is similar to an objection that one often hears propounded against the object-conception (cf. Jackson 1998). Imagine the possibility of panpsychism, i.e. the possibility that all the physical objects of our acquaintance are conscious beings just as we are. Would physicalism be true in that situation? It seems intuitively not; however, if physicalism is defined via reference to the object-conception of a physical property then it is hard to see why not. After all, according to that conception, something is a physical property just in case it is required by a complete account of paradigmatic physical objects. But this makes no reference to the *nature* of paradigmatic physical objects, and so allows the possibility that physicalism is true in the imagined situation.

The first thing to say in response is that the mere possibility of panpsychism cannot really be what is at issue in this objection. For no matter how implausible and outlandish it sounds, panpsychism per se is not inconsistent with physicalism (cf. Lewis 1983). After all, the fact that there are *some* conscious beings is not contrary to physicalism -- why then should the possibility that *everything* is a conscious being be contrary to physicalism? So what is at issue in the objection is not panpsychism so much as the possibility that the paradigms or exemplars in terms of which one characterizes the notion of the physical might turn out to be radically different from what we normally assume -- for example, they might turn out to be in some essential or ultimate respect mental. If that were so, it certainly does seem strange to say that physicalism would or could be true.

Once the problem is put like that, however, it is clear that that the problem has a rather similar structure to other problems that arise when one tries to understand a concept in terms of paradigmatic objects which fall under the concept. Suppose one tried to define the concept red in terms of similarity to paradigmatic red things, such as blood. Pursuing this strategy commits one to the idea that the belief that blood is red is a piece of common knowledge shared among all those who are competent with the term. But that seems wrong -- someone who thought that blood was green would be mistaken about blood but not about red. Now this problem is a difficult problem, however -- and this is the crucial point for our purposes -- the problem is also a quite general problem, and not particularly tied to the notion of the physical. So to that extent, the concept of the physical does not seem to be any worse off than the concept of red. (For discussion of the general strategy see Lewis 1997)

The relation between the two conceptions

Perhaps the most interesting issue concerning the theory and object conceptions of a physical property concerns the question of whether they characterize the same class of properties. There are a number of different possibilities here, not of all of which we can discuss. But one that has received some attention in the literature is that physical theory only tells us about the dispositional properties of physical objects, and so does not tell us about the categorical properties, if any, that they have -- a thesis of this sort has been defended by a number of philosophers, among them Russell (1927), Armstrong (1968), Blackburn (1992) and Chalmers (1996). However, if this is correct, it would seem that the physical properties described by the theory conception are only a sub-class of the physical properties described by the object conception. For if physical objects do have categorical properties, those properties will not count as physical by the standards of the theory conception. On the other hand, there seems no reason not to count them as

physical in some sense or other. If that is right, however, then the possibility emerges that the theory- and the object-conceptions characterize distinct classes of properties.

11. Physicalism and the Physicalist World Picture

Perhaps because of its connection to the physical sciences, physicalism is sometimes construed as an entire package of views, which contains the metaphysical thesis I have isolated for discussion as only one part. If we want a name for the entire package of views including the metaphysical claim we might call it the *Physicalist World Picture*. I will close our discussion of the interpretation question by considering the relation between physicalism (the metaphysical claim) and various other items that at least sometimes have been thought to be a part of the Physicalist World Picture.

> **(a) Methodological Naturalism**: the idea that the mode of inquiry typical of the physical sciences will provide theoretical understanding of world, to the extent that this sort of understanding can be achieved. Physicalism is not methodological naturalism because physicalism is a metaphysical thesis not a methodological thesis.
>
> **(b) Epistemic Optimism:** the idea that the mode of understanding typical of the sciences can be used by us, i.e. by human beings, to explain the world in total, to provide a final theory of the world.. Physicalism is not epistemic optimism because, since commitment to physicalism does not commit you to methodological naturalism, it clearly does not commit you to any optimism about the success of that method in the long run.
>
> (c) **Final Theory**: the idea that there *is* a final and complete theory of the world, regardless of whether we can formulate it. One might think it obvious that if physicalism is true, there is a final theory of the world. However, because of some unclarity in the notion of a theory, the issues here are not cut and dried. According to some views, something is a theory only if it is finitely stateable in a language we can understand. If that is so, clearly physicalism does not entail the idea of a final theory. On a looser conception of a theory, however, it is reasonable to say that physicalism entails that there is a final theory.
>
> (d) **Objectivity:** the idea that the final and complete theory of world, if it exists, will not involve any essential reference to particular points of view or experiences. It is reasonable to say that physicalism entails objectivity. However, given the possibilities of non-reductive or *a posteriori* physicalism even here the issues are not settled. On those approaches, it seems possible to have irreducible points of view or experiences supervening on something physical, which compromises objectivity.
>
> (e) **Unity of Science**: the idea that all the branches of sciences developed by us will or should be unified into a single science, usually (but not always) thought of as physics. This thesis is clearly a methodological thesis about how science ought to proceed. As we have seen, however, physicalism is a metaphysical thesis rather than a methodological thesis

about how science ought to proceed. Hence it is not equivalent to the unity of science thesis.

(f) **Explanatory Reductionism**: the idea that all genuine explanations must be couched in the terms of physics, and that other explanations, while pragmatically useful, can or should be discarded as knowledge develops. Physicalism is not explanatory reductionism because, as we saw in our discussion of non-reductive physicalism, physicalism is consistent with the idea that special sciences are quite distinct from physics. One might say that the special sciences are concerned with patterns in the physical that physicists themselves are not concerned with. For that reason the subject matter of the special sciences is distinct from the subject matter of physics.

(g) **Generality of Physics:** the idea that every particular event or process which falls under a law of the special sciences (i.e. sciences other than physics) also falls under a law of physics. In general, this view presupposes a view about laws and explanation -- for example, it implies or seems to imply that special sciences have laws. But physicalism does not entail any such thesis.

(h) **Causal Closure of the Physical**: the idea that every event has a physical cause, assuming it has a cause at all. Strictly speaking, physicalists are not committed to realism about causation, so they are not committed to causal closure. (Of course, many physicalists do think that causal closure is true, as we will see below, but their position does not entail causal closure.)

(i) **Empiricism**: the idea that all knowledge (with the possible exception of conceptual knowledge) is ultimately founded on sensory or perceptual experience. Empiricism can be given a descriptive or a normative reading. On its descriptive reading, it is most likely false. Most of the information that normal humans come to deploy seems to be caused by of both experience *and* inborn structure and maturation. On the normative reading, the claim is that justification is, at the end of the day, based on experience. But this epistemological thesis has nothing to do with physicalism.

(j) **Nominalism**: the idea that there are no abstract objects, i.e., entities not located in space and time, such as numbers, qualities or propositions. If we assume that abstract objects, if they exist, exist necessarily, i.e., exist in all possible worlds, then supervenience physicalism is completely silent on the question of whether abstract objects exist. All supervenience says is that if a world is a minimal physical duplicate of the actual world, it is a duplicate simpliciter. But if abstract objects exist then they clearly exist in both the actual world and any duplicate of the actual world. What this suggests is that nominalism is a distinct issue from physicalism (Schiffer 1987, Stoljar 1996).

(k) **Atheism:** the idea that there is no God as traditionally conceived. In the 17th and 18th century, physicalism (or materialism, as it was then known) was widely viewed as

inconsistent with belief in God (Yolton 1983). Nowadays, this issue is somewhat less discussed. Nevertheless, as we noted previously, *if* God is thought of as essentially non-physical, then Atheism *does* seem to be a consequence of physicalism, at least on some interpretations of the background modal notions.

12. The Case Against Physicalism I: Qualia and Consciousness

Having provided an answer to the interpretation question, I now turn to the truth question: is physicalism (as we have interpreted it so far) true? I will first discuss three reasons for supposing that physicalism is not true. Then I will consider the case for physicalism.

The main argument against physicalism is usually thought to concern the notion of qualia, the felt qualities of experience. The notion of qualia raises puzzles of its own, puzzles having to do with its connection to other notions such as consciousness, introspection, epistemic access, acquaintance, the first-person perspective and so on. However the idea that we will discuss here is the apparent contradiction between the existence of qualia and physicalism.

Perhaps the clearest version of this argument is Jackson's knowledge argument. (There are also a number of other arguments in this area -- for a very good recent discussion, see Chalmers 1996). This argument asks us to imagine Mary, a famous neuroscientist confined to a black and white room. Mary is forced to learn about the world via black and white television and computers. However, despite these hardships Mary learns (and therefore knows) all that physical theory can teach her. Now, if physicalism were true, it is plausible to suppose that Mary knows everything about the world. And yet -- and here is Jackson's point -- it seems she does not know everything. For, upon being released into the world of color, it will become obvious that, inside her room, she did not know what it is like for both herself and others to see colors -- that is, she did not know about the qualia instantiated by particular experiences of seeing colors. Following Jackson (1986), we may summarize the argument as follows:

> P1. Mary (before her release) knows everything physical there is to know about other people.
>
> P2. Mary (before her release) does not know everything there is to know about other people (because she learns something about them on being released).
>
> Conclusion. There are truths about other people (and herself) that escape the physicalist story.

Clearly this conclusion entails that physicalism is false: for if there are truths which escape the physicalist story how can everything supervene on the physical. So a physicalist must either reject a premise or show that the premises don't entail the conclusion.

There are many possible responses to this argument, but here I will briefly mention only three. The first is *the ability hypothesis* due to Lawrence Nemerow (1988) and developed and defended by David Lewis (1994). The ability hypothesis follows Ryle (1949) in drawing a sharp distinction between propositional knowledge or knowledge-that (such as ‘Mary knows that snow is white’) and knowledge-how (such as ‘Mary knows how to ride a bike’), and then suggests that all Mary gains is the latter. On the other hand, P2 would only be true if Mary gained propositional knowledge.

A second response appeals to the distinction between *a priori* and *a posteriori* physicalism. As we saw above, the crucial claim of *a posteriori* physicalism is that (4) -- i.e. the claim that *S* entails *S** -- is *a posteriori*. Since (4) is *a posteriori*, you would need certain experience to know it. But, it is argued, Mary has not had (and cannot have) the relevant experience. Hence she does not know (4). On the other hand, the mere fact that Mary has not had (and cannot have) the experience to know (4) does not remove the possibility that (4) is true. Hence *a posteriori* physicalism can avoid the knowledge argument. (It is an interesting question which premise of the knowledge argument is being attacked by this response. The answer depends on whether (4) is physical or not: if (4) is physical, then the response attacks P1. But if (4) is not physical, the response is that the argument is invalid.).

A third response is to distinguish between various conceptions of the physical. We saw above that potentially the class of properties defined by the theory-conception of the physical was distinct from the class of properties defined by the object-conception. But that suggests that the first premise of the argument is open to interpretation in either of two ways. On the other hand, Jackson's thought experiment only seems to support the premise if it is interpreted in the one way, since Mary learns by learning all that physical *theory* can teach her. But leaves open the possibility that one might appeal to the object-conception of the physical to define a version of physicalism which evades the knowledge argument.

One of the most lively areas of philosophy of mind concerns the issue of which if any of these responses to the knowledge argument will be successful. The ability response raises questions about whether know-how is genuinely non-propositional (cf. Lycan (1996), Loar (1997) and Stanley and Williamson (forthcoming)), and about whether it gets the facts right to begin with (Braddon Mitchell and Jackson 1996). As against *a posteriori* physicalism, it has been argued both that it rests on a mistaken approach to the necessary *a posteriori* (Chalmers 1996, 1999, Jackson 1998), and that the promise of the idea is chimerical anyway (cf. Stoljar 2000). The third response raises questions about the distinction between the object and the theory conception of the physical and associated issues about dispositional and categorical properties (Cf. Chalmers 1996, Lockwood (1992), and Stoljar 2000, 2001.)

13. The Case Against Physicalism II: Meaning and Intentionality

Philosophers of mind often divide the problems of physicalism into two: first, there are the problems of qualia, typified by the knowledge argument; second, there are problems of intentionality. The intentionality of mental states is their aboutness, their capacity to represent the world as being a certain

way. One does not simply think, one thinks *of* (or *about*) Vienna; similarly, one does not simply believe, one believes *that* snow is white. Just as in the case of qualia, some of the puzzles of intentionality derive from facts internal to the notion, and from the relation of this notion to the others such as rationality, inference and language. But others derive from the fact that it seems difficult to square the fact that mental states have intentionality with physicalism. There are a number of ways of developing this criticism but much recent work as concentrated on a certain line of argument that Saul Kripke has found in the work of Wittgenstein (1982).

Kripke's argument is best approached by first considering what is often called a dispositional theory of linguistic meaning. According to the dispositional theory, a word means what it does -- for example, the word ‘red’ means red -- because speakers of the word are disposed to apply to word to red things. Now, for a number of reasons, this sort of theory has been very popular among physicalists. First, the concept of a disposition at issue here is clearly a concept that is compatible with physicalism. After all, the mere fact that vases are fragile and sugar cubes are soluble (both are classic examples of dispositional properties) does not cause a problem for physicalism, so why should the idea that human beings have similar dispositional properties? Second, it seems possible to develop the dispositional theory of linguistic meaning so that it might apply also to intentionality. According to a dispositional theory of intentionality, a mental concept would mean what it does because thinkers are disposed to employ the concept in thought in a certain way. So a dispositional theory seems to hold out the best promise of a theory of intentionality that is compatible with physicalism.

Kripke's argument is designed to destroy that promise. (In fact, Kripke's argument is designed to destroy considerably more than this: the conclusion of his argument is a paradoxical one to the effect that there can be no such a thing as a word's having a meaning. However, we will concentrate on the aspects of the argument that bear on physicalism.) In essence his argument is this. Imagine a situation in which (a) the dispositional theory is true; (b) the word ‘red’ means red for a speaker S; and yet (c) the speaker misapplies the word -- for example, S is looking at a white thing through rose-tinted spectacles and calls it red. Now, in that situation, it would seem that S is disposed to apply ‘red’ to things which are (not merely red but) either-red-or-white-but-seen-through-rose-tinted-spectacles. But then, by the theory, the word ‘red’ means (not red but) either-red-or-white-as-seen-through-rose-tinted-spectacles. But that contradicts our initial claim (b), that ‘red’ means red. In other words, the dispositional theory, when combined with a true claim about the meaning of word, plus a truism about meaning -- that people can misapply meaningful words -- leads to a contradiction and is therefore false.

How might a physicalist respond to Kripke's argument? As with the knowledge argument, there are many responses but here I will mention only two. The first response is to insist that Kripke's argument neglects the distinction between *a priori* and *a posteriori* physicalism. Kripke often does say that according to the dispositionalist, one should be able to ‘read off’ truths about meaning from truths a physicalist can reject. (For a proposal like this, see Horwich 2000.) However, the problem with this proposal is, as we have seen, that its background account of the necessary *a posteriori* is very controversial. As we saw, *a posteriori* physicalists are committed to what we called the non-derived view about necessary *a posteriori* truths. But the non-derived view has come under strident attack in recent times.

The second response is to defend the dispositional theory against Kripke's argument. One way to do this is to argue that Kripke's argument only works against a very simple dispositionalism, and that a more complicated version of such a theory would avoid these problems. (For a proposal along these lines, see Fodor 1992 and the discussion in Braddon-Mitchell and Jackson 1996). A different proposal is to argue that Kripke's argument underestimates the complexity in the notion of a disposition. The mere fact that in certain circumstances someone would apply ‘red’ to white things does not mean that they are disposed to apply red to white things -- after all, the mere fact that in certain circumstances something would burn does not mean that it flammable in the ordinary sense. (For a proposal along these lines see Hohwy 1998, and Heil and Martin 1998)

As with the knowledge argument, the issues surrounding Kripke's argument are very much wide open. But it is important to note that most philosophers don't consider the issues of intentionality as seriously as the issue of qualia when it comes to physicalism. In different vocabularies, for example, both Block (1995) and Chalmers (1996) distinguish between the intentional aspects of the mind or consciousness, and the phenomenal aspects or qualia, and suggest that it is really the latter that is the central issue. As Chalmers notes (1996; p. 24), echoing Chomsky's famous distinction, the intentionality issue is a *problem*, but the qualia issue is a *mystery*.

14. The Case Against Physicalism III: Methodological Issues

The final argument I will consider against physicalism is of a more methodological nature. It is sometimes suggested, not that physicalism is false, but that the entire ‘project of physicalism’ -- the project in philosophy of mind of debating whether physicalism is true, and trying to establish or disprove its truth by philosophical argument -- is misguided. This sort of argument has been mounted by a number of writers, but perhaps its most vocal advocate has been Noam Chomsky (2000; see also Searle 1992, 1999).

It is easiest to state Chomsky's criticism by beginning with two points about methodological naturalism. In general it seems rational to agree with the methodological naturalists that the best hope for a theoretical understanding of the world is by pursuing the methods which are typical of the sciences. It would then seem rational as a special case that our best hope for a theoretical understanding of consciousness or experience is by pursuing the methods of the sciences -- by pursuing, as we might put it, the naturalistic project with respect to consciousness. So Chomsky's first point is that it is rational to pursue the naturalistic project with respect to consciousness.

Chomsky's second point is that the physicalist project in philosophy of mind is on the face of it rather different from the naturalistic project. In the first place, the physicalist project is, as we have noted, usually thought of a piece of metaphysics. But there is nothing metaphysical about the naturalistic project, it simply raises questions about what we can hope to explain. In the second place, the physicalist project is normally thought of as being amenable to philosophical argument, whereas it is completely unclear where philosophical argument would enter the naturalistic project. In short, there doesn't seem anything

particularly ‘philosophical’ about the naturalistic project -- it simply applies the methods of science to consciousness. But the physicalist project is central to analytic philosophy.

It is precisely at the place where the physicalist project departs from the naturalistic project that Chomsky's criticism begins to take shape. For insofar as it is different from the naturalistic project, there are a number of ways in which the physicalist project is questionable. First, it is hard to see what the project might be -- it is true that throughout the history of philosophy and science one encounters suggestions that one might find out about the world in ways that are distinct from the ones used in the sciences, but these suggestions have always been rather obscure. Second, it is hard see how this sort of project could recommend itself to physicalists *themselves* -- such a project seems to be a departure from methodological naturalism but most physicalists endorse methodological naturalism as a matter of fact. On the other hand, if the physicalist project does not depart from the naturalistic project, then the usual ways of talking and thinking about that project are highly misleading. For example, it is misleading to speak of it a piece of metaphysics and philosophy as opposed to a piece of ordinary science.

In sum, Chomsky's criticism is best understood as a kind of dilemma. The physicalist project is either identical to the naturalistic project or it is not. If it is identical, then the language and concepts that shape the project are potentially extremely misleading; but if it is not identical, then there are a number of ways in which it is illegitimate.

How is one to respond to this criticism? In my view, the strongest answer to Chomsky accepts the first horn of his dilemma and suggests that what philosophers of mind are really concerned with is the naturalistic project. Now, of course, what concerns them is not the details of the project -- that would not distinguish them from working scientists. Rather they are concerned with what the potential limits of the project are.

This is a theme which has reached its best expression in the work of Thomas Nagel (1980, 1984, 1999) and allied work by Bernard Williams (1984). According to them, any form of scientific inquiry will at least be objective, or will result in an objective picture of the world. On the other hand, we have a number of arguments -- the most prominent being the knowledge argument -- which plausibly show that there is no place for experience or qualia in a world that is described in purely objective terms. If Nagel and Williams are right that any form of scientific inquiry will yield a description of the world in objective terms, the knowledge argument is nothing less than a negative argument to the effect that the naturalistic project with respect to consciousness will not succeed.

If what is at issue is the limits of the naturalist project, why is the debate so often construed as a metaphysical debate rather than a debate about the limits of inquiry? In answer to this question, we need to sharply divorce the background metaphysical framework within which the problems of philosophy of mind find their expression, and the problems themselves. Physicalism is the background metaphysical assumption against which the problems of philosophy of mind are posed and discussed. Given that assumption, the question of the limits of the naturalistic project *just is* the question of whether there can be experience in a world that is totally physical. Nevertheless, when properly understood, the problems that philosophers of mind are interested in are not with the framework themselves, and to that extent are

not metaphysical. Thus, the common phrase 'metaphysics of mind' is misleading.

15. The Case for Physicalism

Having considered one side of the truth question, I will now turn to the other: what reason is there for believing that physicalism is true?

The first thing to say when considering the truth of physicalism is that we live in an overwhelmingly physicalist or materialist intellectual culture. The result is that, as things currently stand, the standards of argumentation required to persuade someone of the truth of physicalism are much lower than the standards required to persuade someone of its negation. (The point here is a perfectly general one: if you already believe or want something to be true, you are likely to accept fairly low standards of argumentation for its truth.)

However, while it might be difficult to assess dispassionately the arguments for or against physicalism, this is still something we should endeavor to do. Here I will review two arguments that are commonly thought to establish the truth of physicalism. What unites the arguments is that each takes something from the physicalist world-picture which we considered previously and tries to establish the metaphysical claim that everything supervenes on the physical.

The first argument is (what I will call) *The Argument from Causal Closure*. The first premise of this argument is the thesis of the Causal Closure of the Physical -- that is, the thesis that every event which has a cause has a physical cause. The second premise is that mental events cause physical events -- for example we normally think that events such wanting to raise your arm (a mental event) cause events such as the raising of your arm (a physical event). The third premise of the argument is a principle of causation that is often called the exclusion principle (Kim 1993, Yablo 1992). The correct formulation of the exclusion principle is a matter of some controversy but a formulation that is both simple and plausible is the following:

> **Exclusion Principle**
> If an event *e* causes event *e**, then there is no event *e#* such that *e#* is non-supervenient on *e* and *e#* causes *e**.

The conclusion of the argument is the mental events are supervenient on physical events, or more briefly that physicalism is true. For of course, if the thesis of Causal Closure is true then behavioral events have physical causes, and if mental events also cause behavioral events, then they must supervene on the physical if the exclusion principle is true.

The Argument from Causal Closure is perhaps the dominant argument for physicalism in the literature today. But it is somewhat unclear whether it is successful. The most promising response for the anti-physicalist is to reject the second premise and to adopt a version of what is called epiphenomenalism, the view that mental events are caused by, and yet do not cause, physical events. The argument against this

position is usually epistemological: if pains don't cause pain behavior how can it be that your telling me that you are in pain gives me any reason for supposing you are? It might seem that epiphenomenalists are in trouble here, but as a number of recent philosophers have argued, the issues here are very far from being settled (Chalmers 1996, Hyslop 1999). The crucial point is that the causal theory of evidence is open to serious counterexamples so it is unclear that it can be used against epiphenomenalism effectively.

A different sort of response is to reject the causal principles on which the argument is based. As against the exclusion principle, for example, it is often pointed out that certain events are overdetermined. The classic example is the firing squad: both the firing by soldier A and by soldier B caused the prisoner's death but since these are distinct firings, the exclusion principle is false. However, while this line of response is suggestive, it is in fact rather limited. It is true that the case of the firing squad represents an exception to the exclusion principle -- an exception that the principle must be emended to accommodate. But is difficult to believe that it represents an exception that can be widespread. A more searching response is to reject the very idea of causal closure on the grounds, perhaps, that (as Bertrand Russell (1917) famously argued) causation plays no role in a mature portrayal of the world. Once again, however, the promise of this response is more imagined than real. While it is true that many sciences do not explicitly use the notion of causation, it is extremely unlikely that they do not imply that various causal claims are true.

The second argument for physicalism is (what I will call) *The Argument from Methodological Naturalism*. The first premise of this argument is that it is rational to be guided in one's metaphysical commitments by the methods of natural science. Lying behind this premise are the arguments of Quine and others that metaphysics should not be approached in a way that is distinct from the sciences but should rather be thought of as continuous with it. The second premise of the argument is that, as a matter of fact, the metaphysical picture of the world that one is led to by the methods of natural science is physicalism. The conclusion is that it is rational to believe physicalism, or, more briefly that physicalism is true.

The Argument from Methodological Naturalism has received somewhat less attention in the literature than the Argument from Causal Closure. But it seems just as persuasive -- in fact, rather more so. For how might one respond? One possibility is to reject its first premise. But this is not something that most people are attracted to (or at least are attracted to explicitly.)

The other possibility is to reject its second premise. However, once it is appreciated what physicalism is -- and, more important, what it is not -- it is not terribly clear what this would amount to or what the motivation for it would be. In the first place, our earlier discussion shows that physicalism is not inconsistent with explanatory autonomy of the various sciences, so that one should not reject physicalism merely because one can't see how to reduce those sciences to others. In the second place, while it is perfectly true that there are examples of non-physicalist approaches to the world -- vitalism in biology is perhaps the best example -- this is beside the point. The second premise of the Argument from Methodological Naturalism does not deny that other views are possible, it simply says that physicalism is the most likely view at the moment. Finally, one might be inclined to appeal to arguments such as the knowledge argument to show that physicalism is false, and hence that methodological naturalism could not show that physicalism is false. However, this suggestion represents a sort of confusion about the

knowledge argument. As we saw above, if successful the knowledge argument suggests, not simply that physicalism is false but that any approach to the world that is compatible with methodological naturalism is false. But if that is so, it is mistaken to suppose that the knowledge argument gives one any reason to endorse anti-physicalism if that is supposed to be a position compatible with methodological naturalism.

16. Concluding Remarks and Further Questions

That completes our discussion of physicalism. As you can see, it is sketchy in many places, and this suggests that there is much further work to be done before we arrive at a final assessment of the doctrine of physicalism and the role that it plays in contemporary thought. It may be helpful to end, however, by identifying three areas that seem to me especially deserving of attention in the future.

First, *a priori* and *a posteriori* physicalism. As we have seen, the distinction between *a posteriori* and *a priori* is a crucial one in a number of respects. If *a posteriori* physicalism can be made out, then we have potential answers to both the qualia problem and the intentionality problem. In addition, we have an interpretation of emergentism. On the other hand, it is unclear if the notion is at the end of the day coherent.

Second, the relation between the theory-conception and the object-conception of the physical. As we have also seen, this distinction is an important one in that it allows us to answer the knowledge argument without appealing to the non-derivation view of the necessary *a posteriori*. On the other hand, the distinction is also controversial in a number of respects.

Finally, the relation between objectivity and physicalism. As we have seen Nagel and Williams both think that objectivity is a presupposition of the methodological naturalism that so many contemporary philosophers find attractive. But if that is right there is no point developing a version of physicalism -- or any approach to the world -- that rejects it.

Color

Colors are of philosophical interest for two kinds of reason. One is that colors comprise such a large and important portion of our social, personal and epistemological lives and so a philosophical account of our concepts of color is highly desirable. The second reason is that trying to fit colors into accounts of metaphysics, epistemology and science leads to philosophical problems that are intriguing and hard to resolve. Not surprisingly, these two kinds of reasons are related. The fact that colors are so significant in their own right, makes more pressing the philosophical problems of fitting them into more general metaphysical and epistemological frameworks.

The Philosophy of Color

The visual world, the world as we see it, is a world populated by colored objects. Typically, we see the world as having a rich tapestry of colors or colored forms---fields, mountains, oceans, hairstyles, clothing, fruit, plants, animals, buildings, and so on. Colors are important in both identifying objects, i.e., in locating them in space, and in re-identifying them. So much of our perception of physical things involves our identifying objects by their appearance, and colors are typically essential to an object's appearance, that any account of visual perception must contain some account of colors. Since visual perception is one of the most important species of perception and hence of our acquisition of knowledge of the physical world, and of our environment, including our own bodies, a theory of color is doubly important.

Despite much thought, over thousands of years, by philosophers and scientists, however, we seem little closer now to an agreed account of color than we ever were. The disagreement is reflected in the fact that some theorists believe colors to be perceiver-relative, e.g., dispositions or powers to induce experiences of a certain kind, or to appear in certain ways to observers of a certain kind. Others take them to be objective, physical properties of objects. Among the latter group, some take these properties to be physical microstructures, while others regard colors as sui generis irreducible properties of physical bodies, and yet others take them to be dispositional properties to affect light. Finally, there are even some who deny that there are colors in the world at all: there are none of the colors, it is claimed, that we naturally and normally and unreflectingly attribute to objects.

The major problem with color has to do with fitting what we seem to know about colors into what science, particularly physics, tells us about physical bodies and their qualities. More specifically, we experience color as an intrinsic feature of the surfaces of physical bodies, or as a property spread throughout a volume, e.g., of wine. But, or so it seems, the physical account of these physical objects finds no place for such qualities. It is this problem that historically has led the major physicists who have thought about color, to hold a common view: that the colors we ordinarily and naturally take objects to possess, are such that physical objects do not actually have them. Oceans and skies are not blue in the way that we naively think, nor are apples red, (nor green). Colors of that kind, it is believed, have no place in the physical account of the world that has developed from the 16th Century to this century. Physicists who have subscribed to this doctrine include the luminaries: Galileo, Boyle, Descartes, Newton, Young, Maxwell and Helmholtz. In this doctrine, they were joined by a number of fellow travelers, including most famously, John Locke.

Such a view is clearly paradoxical, given what was said above, about the ubiquity of colors in the perceived world, and about the importance of colors in the identification and re-identification of physical objects. It is possible to mitigate the paradoxical character of the doctrine by drawing a distinction between two concepts of color: (i) color as a sensory quality, intrinsic to our sensory experiences; (ii) color as a power, to induce sensory experiences with color, understood as a sensory quality. On this account, color terms have a systematic ambiguity. Provided we take account of the ambiguity, no harm is done, and much benefit derived. According to this view, then, in one sense of ‘color’, physical objects have colors, for they have the power to induce experiences of color, but in the other sense, they do not. That is to say, there is no problem if the second concept, color-as-it-is-in-experience, is restricted in its use so as to apply to the experiential quality. Problems arise, however, when it is used, naively and unreflectingly, to apply to physical bodies: we naively suppose the experiential quality to be an intrinsic

quality of the physical object. When we enjoy visual experiences, then in some sense we project the sensory quality in our experience on to physical objects. One who exploited this idea to great effect was David Hume, who used our experience of color as a model for thinking about the way we attribute causal connections, necessity and moral predicates to objects and situations in the world (remembering that Hume adapted the model to his own terminology of ‘impressions’ and ‘ideas’).

With this in mind, the Descartes-Locke position is best expressed as implying that it is possible for perceivers when applying color concepts to physical bodies, to use different concepts, reflecting different attitudes which one may adopt. One attitude is what might be called a 'natural' attitude: a naive, pre-reflective, natural attitude; the other involves a more sophisticated attitude. One concept is a pre-reflective, pre-theoretical concept, the other is more sophisticated. While the Descartes-Locke view has had, and continues to have, a strong influence among many of the scientists who work on color, there has always been strong opposition to it among the philosophical community.

Various reasons have been given for dissatisfaction with the physicists' position. It has been variously argued that: (i) the notion of ‘color as it is in experience’ is incoherent; (ii) the physicists' doctrine encapsulates a confusion about what the ordinary, natural concept of color is; (iii) those who defend the doctrine forget that there are other sciences besides physics. For example, there are biological sciences such as zoology, botany, ecology, and so on, in which colors do have a role to play that they do not have in physics and chemistry; (iv) those who defend the doctrine forget that color has a social role to play; that colors are important in social life, and the criteria for application of color predicates are based on that social life; (v) the ordinary, natural concept of color, the ‘folk’ concept is not as the physicists and their friends believe.This last criticism takes several different forms:

1. according to the natural notion, colors are simple, objective, intrinsic qualities of objects, qualities whose natures are manifest in perception: John Campbell, P.M.S.Hacker;
2. according to the natural notion, colors are unknown qualities of physical bodies, qualities which appear to us in distinctive ways: Thomas Reid, Frank Jackson, David Lewis, Brian McLaughlin.
3. according to the natural notion, colors are dispositional properties, powers to appear in appropriate ways: Michael Dummett, Gareth Evans.

The criticism of the physicists' position that their notion of ‘color as it is in experience’ is confused is widely held. [See Westphal (1987), Hacker (1987) and Evans (1980)]. This criticism has in turn been attacked on the ground that it is based on uncharitable interpretations of the texts, ones made without serious attempt to make sense of the physicists' position. [See Maund (1991) and (1995) pp. 6-24; 30-33]

The first of these formulations of the objection, we should note, opens the way for a modification of the physicists' position on color, as expressed by Descartes and Locke. It construes the natural/folk concept of color in such a way that colors are taken to be perceiver-independent, intrinsic, qualitative features of physical surfaces, volumes and other physical entities such as skies, rainbows and flames. This is the kind of color that our visual experiences represent objects as having. The Descartes-Locke position can be reframed so as to adopt this formulation of the folk concept, and to argue that no instances of this concept are physically actualised. According to this way of thinking, Descartes and Locke were right that given

the natural (naive, pre-reflective) concept of color, we can conclude that, in this sense, objects do not have colors. Their way of characterising the concept, however, is at fault. It should not be described as 'color as it is in experience'. There may very well be a coherent notion of 'color-as-it-is-in-experience' or 'color as a sensory quality', but that notion is not the natural concept of color. The natural concept is more plausibly construed as a concept of a certain kind of property: it is a perceiver-independent, intrinsic, qualitative feature of physical surfaces (i.e. it is not a dispositional property either to affect light or to appear to observers). This re-formulation of the Descartes-Locke view may be described as the Illusion theory of Colors.

These theorists can be regarded as being right that there is a natural concept of color which is such that objects do not have colors. It is their way of characterising the concept, however, that is at fault. This concept should not be expressed as "color as it is in experience". There may very well be a coherent notion of "color-as-it-is-in-experience" or "color as a sensory quality", but that notion is not the natural concept of color. The natural concept is more plausibly construed as a concept of a certain kind of property: an intrinsic perceiver-independent feature of physical surfaces (i.e. it is not a dispositional property either to affect light or to appear to observers). It is possible, moreover, to specify the natural concept in more detail: to be red is to have a certain feature, one that satisfies a range of conditions. One such condition is that colors together form a system of qualitative features, that resemble and differ from each other in systematic ways. A second condition is that the color has a causal role to play in the visual identification or recognition of the color.

Given that colors can be specified as properties of this kind, it is then possible to argue that there are no actual properties that satisfy all the conditions set down. Accordingly, those in the Locke-Descartes-Helmholtz tradition who emphasize the need for a distinction between color-as-in-physical-objects and color-as-in-experience are best interpreted as thinking that there is no physical feature in physical objects that satisfies all the requirements (that serves all the required roles) of color, as it is naturally conceived. This reconstruction of the Descartes-Locke preserves the other element of that position, namely that the right way to think of colors is as mind-dependent dispositional properties. This is the best way, it is claimed, to make sense of colors, taken to be properties of physical bodies.

Clearly those in the Descartes-Locke tradition make two substantial claims. One concerns the character of the ordinary, naive, pre-reflective concept of color; the other is a proposal, of what form our color concepts should take, for scientific and metaphysical purposes, i.e., if we want to think clearly and scientifically about colors. the proposal is that color, thought of as a property that physical objects possess, should be thought of as dispositional property: a power to induce experiences of color, in normal perceivers, in the right kind of circumstances. [This concept of color, it should be noted, requires n addition, another concept of color, color-as-it-is-in-experience.]

There is a substantial body of opposition to this element in the Descartes-Locke tradition as well. For some thinkers, the ones referred to above, the opposition is coupled with, and allows for, the ordinary concept. For others, the question of what colors are essentially is decided on grounds separate from the question of how colors are conceptualized, by ordinary perceivers.

We can set out, in summary form, the set of leading rival theories:

1. Colors are objective, intrinsic properties: they are sui generis, irreducible properties, supervenient on microstructural properties of the type cited in 2, below. [P.M.S. Hacker, J. Campbell]
2. Colors are objective, intrinsic properties of physical bodies. They are to be identified with, or are reducible to, microstructural properties of the bodies that possess them. [F. Jackson, T.Reid]
3. Colors are objective properties of bodies but they are dispositional, light-related properties; dispositions to modify light (to emit, reflect, absorb, differentially reflect and absorb, transmit or scatter light), in the right way, and in the right proportion. [D.M. Armstrong, J. Westphal, D.R. Hilbert]
4. Colors are dispositional properties: powers to induce in observers of a specifiable kind, physical responses of a kind that are peculiar to those observers.
5. Colors are perceiver-dependent dispositional properties: powers to appear in distinctive ways, to normal perceivers, in contextualised standard conditions. [M. Dummett, G. Evans, J. McDowell]
6. Colors are perceiver-dependent but hybrid properties: to have a specific color is to have some intrinsic feature by virtue of which the object has the power to appear in a distinctive way (e.g., as in 4). [R. Descartes, J. Locke]
7. Colors are relational properties: they are physical properties, e.g., spectral reflectances, which are perceived in a distinctive way. [E. Thompson, M. Tye]
8. Colors are objective, perceiver-independent properties: they are the occupants of certain perceiver-dependent functional roles, e.g. roles defined in terms of the way objects look. [B. McLaughlin, J.Cohen]
9. Colors are socially or culturally constructed properties. To be red is for an object to satisfy such criteria that make it worthy of having the predicate "red" applied. [J. Van Brakel]

The Aim of Philosophical Theories of Color

To assess the rival claims about the status of color, we need to clarify what the aim of a philosophical theory of color should be. Philosophical discussions of color are sometimes framed in terms of answering such questions as "what is the nature of color?" "what is color essentially?" "what is the essence of color?". Sometimes, they are framed in terms of answering the question of what kind of understanding a person must have in order to understand color concepts or to be able to use color terms with understanding. Here we are asking a question about color concepts and it will be important to clarify first, whether the concepts in question are concepts are concepts of natural language, or technical concepts introduced for scientific or industrial purposes, and then with respect to both, whether there are different kinds of concepts.

On the face of it, there are two different exercises here: identifying the nature of colors, i.e., what colors are essentially; and specifying what the concept of color is. It seems that one exercise requires looking at the world and the other looking at the thinkers. However both exercises would seem to be an integral part of any philosophical theory of color. For there appear to be two prominent facts about colors that any theory would need to respect: (1) that colors are properties in the world (i.e., properties of physical

objects), to which one's color vision is sensitive; (2) that colors are qualities that perceptual experience represent (or presents) objects as having. At least, if any theory denies that these are facts about colors, then an extremely good explanation is called for. One theory that comes close to denying that the first is a fact is the Descartes-Locke tradition. This theory is more subtle, however, than this would suggest. It draws a distinction between two concepts or senses of color. In one sense objects do have colors but this is not the sense in which objects are represented as having colors; while in the other sense, objects are represented as having colors, but these are not properties which objects actually have.

There is a stronger reason for thinking that the two exercises might be related. This reason depends on the fact that there are different available models for thinking about concepts. For certain kinds of concepts, the understanding required in order to possess the concept of X provides the only answer to the question of what X's are essentially. (The nominal essence is the same as the real essence.) On the other hand, if externalists are right then the content of some mental states are broad. Hence, if concepts are constituents of the content then individuating these concepts will require identifying some object, property or natural kind. Accordingly, depending on which model for color concepts we adopt, the two exercises (looking at the world and looking at the thinkers) may be related.

In any case, if those in the Descartes-Locke tradition are right in drawing distinctions between different concepts of color, then there will be different answers to the question of what the essence of color is, depending on which concept we have in mind. There are, within this tradition, two important distinctions. One is between color as a property of physical bodies and color as a quality in experience, i.e a phenomenal or subjective quality: color-as-it-is-in-experience. In the second place, if we concentrate on color conceived as a property of physical bodies, we can distinguish between a naive, pre-reflective concept and a sophisticated, critical concept. For Descartes and Locke, the former concept is confused or at least has a faulty assumption built into it. Accordingly, the answer to the question of what colors are essentially, will be "none" for the pre-reflective concept and "a mind-dependent dispositional property" for the critical concept.

Much of the opposition to the Descartes-Locke account consists in challenging their characterization of the natural or folk concept. Some philosophers, Dummett, Evans, McDowell, argue that the natural concept is dispositional and does not need to be reconstructed in the way that Descartes and Locke suggest. A different form of opposition is found among the many objectivists who claim that the natural concept is objectivist. Opinion divides between those who hold that colors have hidden essences, e.g., microstructural features such as spectral reflectances, and those who hold that their essences are manifest. Most modern objectivists believe not only that colors have essences but that these essences have either been discovered by scientists, or are close to being discovered.

It is possible, however, to take a different view: that the natural concept of color is objectivist, that is, that colors are conceptualized as objective, intrinsic features of physical bodies but, so it happens, there are no such features in nature. The essences are virtual, not actual. On this account, colors are virtual properties (have virtual essences) just as phlogiston and caloric are virtual natural kinds. Given that color perceivers have experiences of color, i.e., experiences which represent objects as having colors, this account implies an ‘illusion theory’ or ‘error theory’ of color experience and perception. Objects are perceived as having

colors which they do not in fact have: there are no such colors.

However the dispute about the natural pre-reflective concept is resolved, we still need to answer the question of how we ought to think of color. If Descartes and Locke are right, then the natural concept needs to be replaced by the critical concept. However, even if they are wrong and dispositionalists such as Dummett and Evans were right about the natural concept, we might want to argue that the concept should be either replaced by, or supplemented by, a reconstructed, revised concept, in the way for example, that concepts of heat, sound, force, and solidity have been refined or revised or supplemented by scientific concepts.

Caution is necessary, however. There appear to be two reasons why there might be a need for a reconstructed concept of color. One could be that the natural concept needs to be eliminated. The other might be that it needs to be supplemented by a new, technical concept. Each reason is related to the fact that the natural concept serves a range of purposes. If it turns out that all, or nearly all, the major purposes are best served by a new revised concept then that would be a case for replacing the old concept. If only certain of the purposes are better served, then that constitutes a case for supplementing the old concept. Given that there is a natural concept of color which is employed both in color vision and in the many social practices concerned with color, then it will be important to specify what the natural concept is, in order to appreciate how if at all it needs to be revised.

It is crucial to remember, moreover, that in the case of color, almost all the purposes to do with colors and hence reasons for having concepts of color have to do with the perception of color. Colors function predominantly as natural and conventional signs, i.e., for various practical epistemological and social purposes. To the extent, therefore, that the natural concept needs to be revised or replaced by any reconstructed concept, the new concept(s) would need to be capable of serving those various purposes. Accordingly an examination of what the natural concept is will be vital for the justification of any theory about how colors should be conceived.

The Natural Concept of Color

The physicists' account of color, both in its original and in its reconstructed version, depends on a certain view of the natural concept of color. So too, in their differing ways, do the accounts of their most important critics. Getting clear about the natural concept of color will thus be essential for resolving that philosophical debate. Quite apart from that, the natural concept is important to describe for its own sake. Getting clear about the natural concept of color is necessary for a philosophical understanding of color.

Discussions of what kind of property color can often be driven by epistemological and metaphysical concerns, which can cause us to lose sight of what seem to be the plainest and most obvious truths about colors. Two of the most obvious truths have already been cited: (1) that colors are properties in the world, (i.e., properties of physical objects) to which one's color vision is sensitive; (2) that colors are qualities that perceptual experience represent (or presents) objects as having. There might be a theory according to which these are not truths at all but only ‘truths’. Such a theory cannot be ruled out, but to be acceptable it

would need to explain why the ‘truths’ have the force that they do as apparent truths.

There is another truth that is more often ignored: that colors play significant roles in the epistemological, personal and social lives of human beings. Colors are important epistemologically, as natural signs or indicators for the identification and re-identification of physical objects. From a social point of view, colors serve a variety of purposes. While retaining their function as natural signs, they also serve as conventional signs, e.g., as badges, uniforms, in ceremony, ritual etc. They may also be said to have a ‘life of their own’. As well as having emotional and aesthetic effects, colors are used in social life to amuse, to entertain, to delight, to shock, to impress, to astound, to warn, to attract, to be enjoyed, and so on, in contexts having to do with pageantry, ceremonial, courtship, painting, lighting, plays, clothing, dining, drinking, and so on.

Recognizing these obvious truths highlights the importance of the natural concept of color, for it is the way in which colors play their various roles that the natural concept is significant. In the first place, colors play their roles through the exercise of color vision, which in turn involves the exercise of color concepts. The perceiver must have perceptual experiences, or acquire perceptual states, which have a certain content. It is through such experiences that colors serve as natural signs, i.e., for the identification and re-identification of objects. Some account needs to be given of what constitutes the content of these perceptual experiences or states, i.e., of what kind of property color is presented or represented as being.

In the second place, there is a wealth of uses for color in our cultural and social life, giving rise to a flourishing color vocabulary. Examples of the sorts of practices are the use of color language, i.e., in the use of predicates such as ‘blue’, ‘red’, ‘white’ etc.; the teaching and learning of color predicates, by the use of paradigm examples; the sorting and classifying of objects; the placing of color samples in ordered structured arrays, the use of colors to impress, delight, astound, court, entertain, and so on. Central among such practices are those involving the use of colors as both natural signs or indicators, and as conventional signs.

If we concentrate on the use of color predicates such as ‘red’, ‘blue’, ‘olive’ etc., in natural language, it is possible to specify what we might call the ‘folk concept’ of color, one expressed by such terms. There is some advantage, however, in using the term ‘natural concept’ to emphasize that the folk concept is built upon the use of a biological endowment, one that is exhibited in the use of colors as natural signs, for the identification and re-identification of physical objects. Whatever it is called, it is clear that, if we wish to give an account of the epistemological, personal and social roles served by colors, then we need to give an account of the natural or folk concept of color, the concept which is embedded in the activities and practices that form the basis of such roles.

To specify the natural or folk concept of color, therefore, requires studying the variety of activities and practices, linguistic and non-linguistic, in which colors play a role. To specify this concept is a central task for any theory of colors to perform. Color is not just a topic for scientific experts. The ordinary folk are experts too. They have expertise in recognizing colors, in sorting and classifying them, in using colors and in responding to them. Color experts are not just those who study color in a scientific way, nor those who paint in colors, nor those who are industrial chemists. There are, in other words, different ranges and

levels of expertise. Those of us who are competent with colors know a lot: we know what color blue is, how it differs from red and from yellow and green; we know how dark blue differs from light blue; we use terms such as rich, pale, faded, intense, brilliant, bright, pure, mixed, and so on to convey and exploit what we know.

Recognizing the expertise of the ‘folk’ should also make us alert to the dangers of using the term "the folk concept" of color. The term ‘natural concept’ is much safer to use. For one thing, ‘folk concept’ gets easily conflated with ‘folk theory’, i.e., some doctrine that we in our naive moments would articulate if asked, and if we had the time to reflect on. There are two things wrong with this slide. In the first place, the natural concept is a concept (or set of related concepts) not a theory (though its possession may presuppose certain beliefs). In the second place, by calling it a theory, it is easy is to over-intellectualize the concept. The concept is one embedded in a vast set of conceptual practices, engaged in by color experts, those who are competent in the perception, recognition and use of colors. The knowledge is implicit as well as explicit, and it involves know-how besides.

In providing an account of the natural/folk concept of color, there are two sorts of description that we can provide: (i) a description of the way color is conceptualized, i.e., the kind of property color is conceptualized as being; (ii) a description of the kind of concept the natural/folk concept is, i.e., a description of how the concept is acquired, how it is exercised, the purposes it serves, and so on. In this respect it is possible to describe the folk concept of color as follows:

1. color concepts are perceptual concepts;
2. color terms such as ‘red’, ‘green’, ‘blue’, etc are taught by the use of paradigm examples;
3. there is a distinctive color vocabulary the terms of which are taught by paradigm examples.
4. it is through the exercise of color concepts (through the way colored objects appear), that colors fulfil their (practical) epistemological role: to serve as the signs for identification and re-identification of physical objects.
5. it is through the exercise of color concepts (through the way colored objects appear), that colors fulfil their social roles: to serve as conventional signs
6. it is through the exercise of color concepts (through the way colored objects appear), that colors fulfil their aesthetic and emotional roles.

It is through the study of the activities and practices which involve the acquisition and exercise of such concepts, that we can state certain principles about the kind of properties colors are conceptualized as being. These principles are implicit or explicit in the activities and practices. One such principle is that colors are perceptually salient, i.e are the sorts of properties that color vision is sensitive to and which are presented or represented in perceptual experience. Other important principles are those having to do with fact that colors as a group form structured arrays, with characteristic internal structures.

This last feature is perhaps the most significant feature about colors, the colors objects are represented as having. Colors are properties that as a group, form an internally-related 4+2 structure, built on the four unique, primary hues: green, red, blue and yellow, and related to the black/white pair. Colors can be placed in systematically ordered arrays, along three dimensions, e.g., hue, saturation, and brightness.

There are different arrays according to whether the colors are surface colors, film(aperture) colors, volume colors, light colors etc. Each array has a distinctive, complex character: a fourfold structure, based upon four distinctive, unique hues: green, red, blue and yellow. All colors can be mapped according to how near to or far from they are to any two of these unique, primary colors. Moreover, more than one such color system can be constructed even for the one mode of appearance: the Oswald, Munsell and Swedish Natural Color systems are examples. The last-named for example, uses dimensions of hue, chromaticness and whiteness/blackness, whereas the Munsell system uses hue, chroma and lightness. These dimensions are most suitable for surface colors, whereas hue, saturation and brightness are more appropriate for aperture colors.

In short, we can state that, given the natural/folk concept of color, colors are the following kind of properties:

1. Colors are perceptually salient:
    - they are the sorts of properties that one discerns directly by looking, that one recognizes the objects as having.
    - they are qualities that are presented (or represented) in visual experiences. Visual experiences characteristically are experiences of colors, and of shapes and other qualities of objects in a 3-dimensional space.
    - they are properties causally connected with perception and identification of specific objects as red, yellow, blue, and so on.
2. Colors are the sorts of properties that can be arranged systematically in ordered arrays. That is, a set of internal relationships hold between the range of colors.
3. Colors comprise the kind of property which make true a wide range of first order color principles or statements. Some examples are the following:
    - tomatoes are red, so are sunsets and blood, and so on.
    - red merges gradually into yellow in one direction, and into blue in another direction, but not into green except through either yellow or blue; and so on.
    - ripening bananas goes from green to yellow, certain ripening apples go from green to red, and so on.

The statements cited in 3 are meant to be illustrative examples. There is a considerable variety in the types of statement involved. Some are causal truths e.g., ripening pears and wheat go from green to yellow, acids turn blue litmus paper red, spiders with red stripes on the back are venomous, black hair tends to grow grey with age, and so on. In the second place, there are certain aesthetic and emotional facts. For many people, green is soothing. Soft pastels are suitable in certain contexts; mauves and browns are not. Light colors and dark colors have different effects on mood, and so on. Certain colors are harmonious, and others jarring. In addition, there are truths comprising the way perceived colors vary with illumination, distance, orientation, and so on. There are other truths concerning how the color of surfaces is affected by the background against which an object is seen.

What has been just given is a partial characterisation of colors, given the natural or folk concept of color. It is plausible to hold that a fuller characterisation than this minimalist version can be provided.

Unfortunately any such account is likely to be controversial. Frank Jackson (1996) describes what he calls ‘a prime intuition’ about colors that there is something peculiarly visually conspicuous about colors: "Redness is visually presented in a way that having inertial mass and being fragile, for instance, are not, When we teach the meanings of the color words, we aim to get our hearers to grasp the fact that they are words for the properties putatively presented in visual experience when things look colored." [p. 199.] This prime intuition, Jackson states, is simply that red is the property objects look to have when they look red. This deceptively simple prime intuition is said to tell us something important about the metaphysics of color when we combine it with plausible views about what is required for an experience to be the presentation of a property: a necessary condition for experience E to be the presentation of property P is that there be a causal connection in normal cases. [p. 200.]

The idea behind talk of ‘prime intuitions’ is that they are the intuitions formed by those competent in the use of color language, especially in the identification and recognition of colors. Those competent perceivers and users of color language are persons capable of reflecting on the way in which colors are presented (or represented) in color experience. Accordingly, it is plausible to hold that colors are presented as follows: as objective, perceiver-independent, intrinsic features of physical bodies, i.e., physical surfaces, volumes, light sources, illuminations, films, media, and so on.

The expression of this intuition adds little to the previous minimalist characterisation of the folk/natural concept of color. It is plausible to go further and hold that colors are not only intrinsic features of physical bodies, but are presented as manifest, sensuous properties. The way they are manifest is that their nature is open and manifest, not hidden. Some philosophers are prompted to respond to this claim by saying that it begs the question against those theorists who hold that colors have hidden essences, e.g., physical microstructures. The counter-reply to this response is that the view that colors have hidden essences is not the right theory about the natural concept or folk concept of color. It may be plausible as a theory of what a reformed concept of color is or should be, but not as a theory of what the folk concept is.

Admittedly it is not easy to convince people that there are manifest properties. One of the problems is that many concepts begin their life as concepts of manifest properties, but then evolve into more complex concepts. Children's concepts of say ‘horse’, ‘dog’, ‘man’ and so on, are cases in point. For them, the concept is almost exclusively defined by the corresponding appearances. There are, however, more sophisticated examples. Take concepts such as brilliant, dazzling, sprightly, po-faced, cheery, glum, picturesque, grim-faced, pale, etc. These are terms that characteristically apply to appearances. All of them, it is plausible to suggest, are manifest properties with essences they ‘wear on their faces’, and are not hidden.

Many properties are not manifest: being poisonous, being made by a robot, containing water as a constituent, coming from Virginia, and so on, but some clearly are. Included among these are colors. Someone who is taught color terms and who understands how they are used, knows what it is for something to be red, to be blue, or whatever: it is to have that feature which the perceiver is capable of recognizing. Reflecting on the way colors are represented, the thoughtful observer can say that the sort of property colors are represented as being are as color ‘stuffs’ spread on the surface of physical bodies (or through volumes, etc.). They are intrinsic features of physical surfaces (volumes, . . .), spread over the

surface. It seems only too clear that we experience the redness of a ripe apple as an objective quality of the apple, the redness being in an objective space just as much as are the shape, the contour, the texture of the apple. This point can be neatly illustrated by quotes from two eminent workers on the physiology/psychology of color, Hering and Boynton. Hering for example, writes:

> When we open our eyes in an illuminated room we see a manifold of spatially extended forms that are differentiated or separated from one another through differences in their colors . . . Colors are what fill in the outlines of these forms, they are the stuff out of which visual phenomena are built up; our visual world consists solely of differently formed colors; and objects, from the point of view of seeing them, that is, seen objects, are nothing other than colors of different kinds and forms. [Hering (1964), p. 1]

In similar vein, the physiological psychologist Robert Boynton writes in ‘Color in Contour and Object Perception’: "From early childhood we are easily able to recognize a property of objects, usually associated with their surfaces, that we call color. No child, and relatively few adults, will doubt that color is on (or sometimes in) objects." [Boynton (1978), p. 175] In addition, one is aware of the different character of the way colors appear in different modes, i.e., for object surfaces such as apples, patches of light on screens, volumes such as wine, scattering media such as skies, light sources such as globes, and so on.

There is one more prime intuition which is one of the most important. It is part of the folk concept, another ‘prime intuition’, that colors are represented as qualitative, sensuous features. This point will no doubt be controversial, but it ought not be. Reference to the sensuous nature of colors is crucial. These qualitative features that colors are represented as being are ‘sensuous’ in the widest sense. This is not an issue of deep metaphysics. The term "sensuous" is often used on such a way as to apply to phenomenal, i.e., to ontologically subjective qualities. However, there is a wider sense which does not have this commitment. There is a neutral use for the term. An illustration is an example which H.H.Price borrows from Husserl: ‘When I see a tomato hanging on a vine then a ripe tomato hanging on a vine is "leibhaft gegeben": it is given to me with its sensuous qualities.’ [Price (1932), p. 231.] This sound much better, of course, in German, but in English the point is that the tomato (better still, grapes) and the vine are given in perception with the sensuous features. English speakers understand that in perceiving tomatoes, grapes, etc one is acquainted with sensuous features. Price was acknowledging that whatever one's theory of perception, and especially whether one thought that the perceiver is directly aware of physical objects or sensory presentations, one was acquainted with sensuous features.

A similar point is made by Evan Thompson (1995) though with respect to the term ‘phenomenal’, rather than ‘sensuous’. Research in psychophysics and visual physiology, he writes, is constrained by the ‘phenomenal structure of color’. By this term he means to refer primarily to the three dimensions of color, known as hue, saturation and lightness, as well as to the relations that colors exhibit among themselves (p. 39). As he points out, textbooks often classify these properties of color as ‘subjective color phenomena’ or as features of ‘color experience’. Thompson prefers to use the term ‘phenomenal’ to describe them because they are first and foremost features of how colors appear: "I thus intend to use the term ‘phenomenal’ in its older sense of pertaining to appearances, not in the current sense of subjective."

The neutral notions of ‘sensuous’ and ‘phenomenal’ are ones that can be shared by writers with very different philosophical commitments. It is such a notion that Michael Tye employs, when he states that when philosophers appeal to the phenomenology of perceptual consciousness, in making claims about the phenomenal character of experience, they are mistaking intrinsic features of the content of experience for intrinsic features of experience itself.

Accordingly, we can represent writers as diverse as Price, Thompson and Tye, despite their philosophical differences, as in agreement. There is a neutral sense of ‘sensuous’, or ‘phenomenal’, according to which it is possible for physical objects to have sensuous or phenomenal properties. Most importantly, the color properties that the natural concept of color attributes to physical objects are sensuous properties. It is of course a separate question of whether physical objects do have the sensuous features that they are represented as having. Price thinks that they do not, but he also thinks that a further argument is required to show that they are not.

To conclude: given the characterisation of the natural concept of color, color is a certain kind of property. Which kind it is can be specified, in part, by saying that it is an objective, perceiver-independent, manifest and sensuous kind. In addition the property is one with certain kinds of causal powers vis a vis the presentation of color in the perception, recognition and identification of colors. Finally, colors are the kinds of properties that fit together in characteristic ways to form structured color arrays, with a distinctive 3-dimensional character. They are properties that as a group, form an internally related 4+2 structure, built on the four unique, primary hues: green, red, blue and yellow, and related to the black/white pair. Some parts of this characterisation of the natural concept are contentious, e.g., the claims that colors are manifest and sensuous. Some of the most significant parts of the characterisation which have the most far-reaching implications are not controversial: that colors have causal powers as described above, and that collectively form astructured system.

Science of Color or Color Science?

There is a flourishing field of color science, one that goes back to Newton and includes such famous figures as Young, Maxwell, Helmholtz, and Hering. Almost all of this field has to do with the perception of color, that is, to studying the conditions that cause or contribute to colors being seen, or to ways in which the colors as they appear may be studied. An example of the second kind of research is the many studies in colorimetry, involving the specification of colors. Typically these involve matching techniques in which the subject is asked to match some stimulus with one or another of a range of standardized cases.

One of the most vigorous areas of research, especially more recently, is the study of color vision, i.e., of the mechanisms involved in the perception of color. Helmholtz and Hering were pioneers in the physiology of this area, but much has been done recently in research on the neural processes involved in color perception. A crucial development has been the growth in opponent-process theory. [See Kaiser and Boynton (1996) for technical discussion. See Hardin (1988) and Thompson (1995) for philosophically-informed discussions.] Also of significance are the experiments by Land and his colleagues and the

development of his retinex theory of color vision. [See Land (1983) and also Hardin (1988) and Thompson (1995) for critical discussion.] Uncovering the mechanisms that underlie color vision is an exciting current field of research. The major philosophical relevance of such research is that it promises to help explain why some of the appearances of color have the character that they do, e.g., why there are no reddish-greens nor bluish-yellows. If it becomes clear that appearances have a certain character which no set of objective physical features have, and that character can be found to based on the physiological/neural processes, then the research may be crucial in establishing that color is best thought of not as some objective feature of the world that color vision detects, but rather as something constructed by one's color vision.

Another area of color science has to deal with the construction of color systems, i.e., of ways of ordering the range of colors in a systematic fashion. Usually this is done by constructing three dimensional color solids. It is interesting, however that there are different systems that have been constructed. For one thing different dimensions are used depending on the way in which color appears. Colors as properties of surfaces, in general, have a different mode of appearance from colors as properties of volumes such as wine, and yet again from that for film color or aperture color. These different modes of appearance suit different dimensions of color. For surfaces the dimensions (at least in some systems) are hue, chromaticness and whiteness/blackness; for aperture or film colors the dimensions are hue, saturation and brightness.

Yet another field in which the way colors appear is crucial is the field of color psychology: the field in which color-constancy, simultaneous contrast, the effects of various backgrounds on color perceptions, and so on, are examined, and competing explanations debated.

Almost all of this research in color science is devoted to the way color appears, i.e., to the conditions under which one perceives color or experiences it or to the character of the way color appears. Almost none of it is concerned with the other color ‘truths’, that is, to what we might call ‘causal truths and principles’. This is not to say that those ‘truths’ or principles are false or are invalid. Biology and chemistry and indeed physics all use color concepts and claims in their theories (some of them) and explanations, but there has not developed what might be called a "science of color", except for the study of the way color appears, or one might say, of the way colors are represented, and of the causes and conditions conducive to the way they appear and are recognized. That there is a flourishing field of color science but not a science of color reflects the special place color has in science.

There is an important difference between color science, on the one hand, and the science of shapes, geometry, the science of heat and temperature, and the science of sound, on the other hand. In the case of shapes and heat/temperature, and sounds and weights, we have properties of physical objects which we can detect, naturally and unreflectingly, by the use of our senses. These properties, however, are different from colors. In the case of shape and heat and weight and sound, there has developed a science in which the principles of sound, weight, heat, and shape are studied. There is however no parallel science of color. There are few color principles to serve as the basis for a science of color. Color science is a large field, but it is built around the way that colors appear and to the conditions under which colors can be perceived, and the causes which lead to the perception of colors. If colors ceased to appear in the

distinctive ways then color science would disappear.

The field of color science has developed through building up theories and color facts which contribute to our understanding of the perception of color, as well as to provide an objective specification of color. With both aims, the scientific account has to take account of a range of color facts that hold of the practices and behaviour of color-perceivers. That is, before we discovered any detailed scientific knowledge about color, we had - and still have - a considerable body of knowledge about color.

This body of color knowledge is contained within the conceptual practices specific to color. By studying these practices, we can draw up a set of general color principles and 'truths'. The range and extent of the general principles, have been emphasized by Justin Broackes (1992). [For further discussion, see Maund (1995).] These general facts or principles include causal truths, although the nature of the causal powers may be difficult to discern. It is easy to see that color science has both filled out the details of some of the color principles described previously, e.g., in respect to the internal relations and to the conditions under which color is perceived, and in some case modified them. Furthermore, the discovery of color-mixing laws and of the mechanisms underlying color vision has added to our knowledge of color.

A Unifying Framework for Colors

There is a set of color truths and color principles that can be said to comprise our color-knowledge. It is to this body of knowledge that color science contributes. It is possible to find some unifying order that brings together in a unitary scheme these various color truths and principles. The set of truths and principles can be divided into separate categories, which bring out the different roles played by colors and color-concepts in (i) the acquisition of color terms in language; (ii) the appearances of colors (iii) the development of first-order truths or 'truths' about colors and (iv) servicing social and epistemological purposes.

L: Principles about the Use of Color Terms:

1. Color terms are taught and learned by the use of paradigms. This is to say that the paradigms are identified and recognized by the way they look (appear).
2. Colors are properties of bodies that play a causal role in the learning of color terms and the communication about colors.
3. Cross-cultural comparisons indicate that there are certain basic color terms which are systematically related. [See Berlin and Kay (1969), and Boynton and Olson (1990), and for a contrary view, Van Brakel (1993)]

A: Principles about Appearances and the Perception of Color:

1. Specific colors have distinctive appearances, characteristic of each color.
2. The way colors are identified and recognized is by the way they appear to perceivers. There are no color thermometers or other measuring devices.

3. Colors take a different mode of appearance, i.e., have a different characteristic appearance, when they are features of physical surfaces, films, volumes, light sources, etc.
4. There are principles governing the conditions under which colors are perceived. Certain conditions are better than others for identifying colors; certain people are better than others at identifying colors. Colored bodies can appear differently when viewed at different distances, in different illuminations, and against different backgrounds.
5. Among the principles in A4 are principles governing constancy effects: tendencies for objects to look the same under different conditions.
6. There is a certain distinctive form to the way colors appear. Visual experiences represent colors in a certain way, as qualitative features which are "sensuous" in the widest sense.

T: Color Truths of the First Order:

1. There is a vast range of specific color truths: ripe bananas are yellow; certain sunsets are golden; claret wine is claret red and so on.
2. Colors can be combined together in structured, systematically ordered arrays, with a distinctive character. They are qualitative features which are "sensuous" in the widest sense. These arrays are different depending on whether the colors are colors of surfaces, volumes, films, scattering media, lights and so on.
3. There are general causal truths e.g., ripening pears, bananas and wheat go from green to yellow, acids turn blue litmus paper red, spiders with red stripes on the back are venomous, black hair tends to grow grey with age, and so on.
4. Different colors have different specific aesthetic effects, including principles of harmony, balance, contrast, etc.
5. Different colors have different emotional effects.

R: Principles about Colors and Their Roles:

1. Colors are natural signs, i.e., are easily identifiable features of objects that enable perceivers to identify and re-identify kinds of objects.
2. Colors serve as conventional signs, for similar purposes as those in R1.
3. Colors, often because of effects in T4 and T5, serve certain social and psychological roles.

It needs to be emphasized that these categories are not meant to be exclusive. For example, principle R3, concerning the social and psychological role of colors is related to principles T4 and T5, concerning the specific aesthetic and emotional roles of colors. Likewise the principles in A6 and T2 both refer to the sensuous nature of colors.

The Illusion Theory of Colors

The natural or folk concept of color conceptualizes color as a certain kind of property: an objective, perceiver-independent, intrinsic feature of physical bodies. The property is, moreover, one with a certain character and with certain causal properties. The most straight-forward view of colors is that they are what they seem. Colors are properties whose essences are manifest. Since colors here are taken to be simple, primary quality of objects, we might call this view "The Simple Objectivist View of Color". It stands in clear contrast to those forms of Objectivism according to which the essences of colors are hidden, not manifest. [See OBJ].

Opposed to both forms of Objectivism is another view: ‘The Illusion Theory of Colors’. In this account, it is held that once we spell out the character of the features specified by the folk or natural concept, we discover that there is in nature no such features: colors as they are conceptualized are properties not found in nature. The colors objects are represented as having, in visual experience, are ones that no object actually has.

The natural concept of color conceptualizes color as a certain kind of property. Which kind it is can be specified, in part, by saying that it is an objective, perceiver-independent, manifest and sensuous kind. In addition the property is one with certain kinds of causal powers vis a vis the presentation of color in the perception, recognition and identification of colors. Finally, colors are the kinds of properties that fit together in characteristic ways to form structured color arrays, with a distinctive 3-dimensional character. They are properties that as a group, form an internally related 4+2 structure, built on the four unique, primary hues: green, red, blue and yellow, and related to the black/white pair. Some parts of this characterisation of the natural concept are contentious, e.g., the claims that colors are manifest and sensuous. Some of the most significant parts of the characterisation which have the most far-reaching implications are not controversial: that colors have causal powers as described above, and that collectively form a structured system.

Defenders of the Illusion Theory of Color exploit the presence of these features in the natural concept to argue that, given this concept of color, there are in fact no colors in nature, that objects are presented in experience as having colors which neither they nor any object have. Crucially, there are no properties that both have the causal powers in question and which collectively have the right character. In short, there are no colors that are intrinsic, non-relational, perceiver-independent properties and which satisfy the requirements of the three-dimensional color solid. None that is, that allow us to make sense of the way in which we perceive and identify and recognize colors.

No properties of physical objects stand, it has been said, in the right kinds or relations that are characteristic of the structured color arrays. It is true that we can arrange physical samples in ordered arrays but the ordering principles depend on the way they appear. What is crucial to the principle of ordering is the way the colors are represented as being, or rather, the character of the way colors are represented. It is because there is a distinctive appearance associated with each color that the colors are capable of being systematically ordered in the way that they are.

It would seem that, as far as our conceptual practices governing color are concerned, physical objects do not have the kinds of color they are represented as having. The colors that objects are represented as having are illusory: no physical object actually has those colors. The colors might be said to be "virtual properties": they are properties objects do not have, but might have had: in some other possible world but not in this one. If we speak of colors as having essences, then they have virtual essences. Colors are virtual properties, just as phlogiston and caloric are virtual natural kinds.

The illusion theory, or virtual essence theory, of colors leaves us with a problem. If there are no properties that satisfy the requirements for being colors: how did the natural concept develop? The solution to this problem is found in the fact that the way that the concepts of color operate, to serve their various functions and roles, is through the way colors appear. For these purposes and roles, objects do not need the actual colors. It will be sufficient if they appear to have colors. For these purposes, it is sufficient that "it is as if they have the colors".

There are two major functions for color concepts. One reflects an epistemological purpose: colors are signs used to indicate the presence of objects of interest. The signs are either natural or conventional, the latter being ones designed for various social purposes. The purposes are equally well served even if objects do not have colors, but have the right appearances. All that is needed is that they are represented as having colors. The second major purpose of color concepts is aesthetic, understood in the widest sense. Color is significant in painting, decorating, clothing, theatre, make-up, advertising, showing off, sexual appeal and so on. Again, it matters not in the least that objects do not have these properties. All that is required is that they be represented as having them.

The significance of appearances is widespread. As we have seen, they provide the basis for the ordering principles governing color systems. Likewise, the causal truths and principles that employ color terms are ones connected with the way colors appear. For example, we can explain how there are such ‘truths’ as "ripening pears (bananas, . . .) go from green to yellow". This is a truth. For a pear to be represented as green under the right conditions is a sign that the pear is not yet ripe; for it to be represented as yellow is a sign that it is ripe. In other words, whatever causal truths we have concerning color, can be explained by interpreting colors as signs or as indicators for other physical features, where those physical features serve the causal roles.

In a previous section a distinction was made between color science and the science of color. While the former field is flourishing there is little science of color. One way of understanding how this situation has arisen is that there are no actual colors in physical reality. What there are are experiences which represent objects as having colors, colors which in fact they do not have. That is, colors are virtual properties. Our visual experiences present us with systematic illusions. If this were the case, we would still have the same color science, exactly as we have now, for we would still need to know how colors are represented, and what causes them to be represented in the way that they are, and how the various conditions under which we have color experiences systematically differ can be explained. Since one of the central roles colors serve is to act as signs or indicators for physical objects, and any theory of color has to acknowledge this role anyway, it would seem that any fledgling science of color is best dispensed with in terms of other

sciences, and color science left to the science of color perception. This does not stop it from being the case that there is an important theory of color vision and perception, and of the role colors play as signs or indicators.

Clearly, the concept of color can be used to serve many of its normal purposes even if the representations of color are illusory, provided that the illusions are systematic, which on a proper theory, of course, they will be.

Colors as Simple Intrinsic Objective Qualities

The Simple Objectivist View of Color is that there are in nature colors of the kind specified by the natural concept. Colors are simple intrinsic, non-relational, non-reducible properties, supervenient on micro-physical features. Such a view has been presented by P.M.S. Hacker (1987) and by J. Campbell (1994).

The main problem the illusion theorist finds with the Simple Objectivist View is with reconciling the putative character of the intrinsic color features that fit together to comprise color solids with the distinctive structure, with the causal role of such features in the recognition and identification of colors. The problem is addressed by Hacker in his defense of the claim that colors are intrinsic features of physical bodies. He forthrightly rejects not only the physicists' view, and Reid's view on colors, but also the dispositionalist account offered by McGinn, McDowell and Dummett. He insists that colors are properties which are used to provide causal explanations. There is no more reason to deny this, he says, than there is to deny the parallel claim for solidity and liquidity. In particular, he claims that we can provide causal explanations for why colors affect color perceivers. The explanation is not vitiated by the discovery that microstructural processes are involved, any more than explanations concerning solidity and liquidity are rendered otiose by the discovery of the microstructural base for these properties.

It is doubtful that this maneuvre works, for a number of reasons. One is that we would need to specify the criteria that make it the case that an object is intrinsically red. Not all perceivers agree in their judgements. It is not that there are color blind people who can, after all, be said to be color-deficient. There is a small but still significant number of color-anomalous people, who can make all the same color discriminations as regular people, but who disagree about which samples are pure red, green, etc. That is, it seems that their color solid is skewed from the normal. It seems arbitrary that we decide that the real color is the one that the majority pick. Secondly, if there were an evolutionary shift, or an eugenics program, the minority could become the majority.

There is a more important reason against Hacker's proposal, however, which depends on the fact that for colors, microstructural explanations cannot be provided for all the relevant, important features. Specifically the complex internal relationships between the colors cannot be explained by the microstructural properties of physical bodies, except through their affecting the perceivers. That is, to explain why the colors have the relationships they do requires giving an account of the structure of the perceiver's perceptual apparatus. At a minimum, this requires an account of the response curves of cells in the retinae, but also required would be an account of the appropriate neural processes. In short, the

explanation will have to work via an explanation of how things appear, that is, of how one's perceptual experiences have the content that they do.

There is a difference between solidity/liquidity and the colors. In the case of solidity and its sister concepts, there is a range of features that are associated with them, including causal relationships. If we have been given adequate scientific explanations at the microstructural level for solidity, then adequate microstructural explanations will need to be given for these other features. The reason why it is important to preserve the concepts of solidity and liquidity is that such concepts unify sets of properties that are useful to have unified, and this unification is lost if we retreat to the microstructural level.

The important difference for colors is that there are crucial features of colors that are not reproduced at the microstructural level of the physical objects, nor are they explained at that level. The features are those that colors have, by virtue of which they are capable of forming systems of properties with internal relationships. This structural property is not explained at the microstructural level of physical samples of colors. To try to explain the structure physically, the best we could hope to do is to try to explain it in terms of dispositions, e.g., to induce a certain ratio of light sensitive retinal cells. Even if that were to work, it is the wrong kind of explanation to help Hacker. He wants to hold that colors are intrinsic qualities of physical objects, not relational, dispositional ones.

Objectivism

The Simple Objectivist view is that the objective essences of colors are manifest. The more common form of objectivism, however, is that colors have hidden objective essences. Advocates of this view have differed, though, on whether the hidden essence of color is a microstructural feature, intrinsic to the colored body or whether it is a light-related dispositional property, e.g., one connected with reflectance profiles. Thomas Reid was probably the earliest example of the first type and Frank Jackson (1996) the latest. Recent examples of the second type are D.M. Armstrong (1969), J. Westphal (1987) and D. Hilbert (1987).

The attempt to locate the essence of color among the microstructural features of colored bodies seems unpromising. One of the major problems is ‘the problem of multiple realizations’. Given the range of bodies that have colors _ surfaces, volumes, light-sources, illuminations, luminescent bodies, films, expanses _ the intrinsic physical features that provide the causes for the way colors appear show a bewildering variety. Even if we concentrate on the first type of color, surface color, : we find that there is a wide variety of underlying physical microstructures, responsible for objects' appearing blue, yellow, etc. The causes of the colors objects appear to have are many and varied. The same type of micro-structure consistently appears the same color (within limits) under different conditions, but different microstructures may appear the same.

It would seem, therefore, that the most plausible candidates for objective essences are light-related dispositional properties, e.g., capacities to emit, reflect, absorb, transmit or scatter light to varying degrees. However, the problem of multiple realizations has merely been postponed for, depending upon

the type of object in question, a different candidate for the objective essence has to be found. For physical surfaces, it would have to be related to the object's reflectance curve, e.g., the capacity to differentially reflect wavelengths from different regions of the incident illumination; in the case of volumes, it would be related to the object's transmittance; in the case of such objects as the sky, to the scatterance; in the case of aperture color or film color, it would be related to the pattern of light received at a particular place or at the source of the light (the reflecting source in the case of physical surfaces) and so on. Even in the case of ordinary objects, the colors may be caused in a variety of ways. The blue of a bird's coat may result from scatterance, the red in a different way.

Nevertheless, progress can be made if we concentrate on one type of color, surface color. The most plausible attempt is to try to identify surface color with a light-modifying disposition, e.g., with a disposition to reflect (or absorb) certain proportions of standardized illumination, or, if one prefers, certain proportions of light of the wavelengths from the visible spectrum. Objects with neutral or achromatic colors are ones which reflect all wavelengths to (roughly) the same degree, with whites reflecting a higher percentage than greys and blacks. Objects with chromatic colors are those which differentially reflect or absorb light at different wavelengths. Accordingly surface color would be identified with some feature of an object's spectral reflectance curve.

A special case of the problem of multiple realizations is posed by the occurrence of metamers. In the case of physical surfaces there are metamers, i.e objects with very different reflectance curves that have identical appearances of color. The situation is far more pronounced in the case of film colors or aperture colors. Here there are innumerable different combinations of light that will give the same hue. It would seem that the property shared by physical objects with the same film color is a disposition to incite the three light-sensitive cones in the retinae according to the same ratio: x: y: z.

The major problem, however, with any of the objectivist accounts of surface color is that, given the way the natural or folk concept has been characterized, it is hard to see how there could be an objective essence with the right characteristics. For, given the natural or folk concept of color, it seems that color is a certain kind of property: a perceiver-independent, intrinsic property of objects, one that satisfies certain constraints. But it is hard to see how there could be any intrinsic, physical features that satisfy all the constraints. The most crucial requirement is that colors, as a group, have to stand together in the right kind of relationships. There are no manifest, intrinsic features that satisfy this requirement. Nor does any set of microstructures stand the remotest chance of satisfying the appropriate constraints. In particular, there are no physical features, either of microstructure, or of the object's contribution to light, such that the right kind of internal relationships hold. [See Hardin (1988) and Maund (1995).] Neither can color be a dispositional property, say spectral reflectance, or a disposition to produce physiological responses of a certain kind, since spectral reflectances don't fit together in the right kind of ways.

There are two kinds of response an objectivist might make. One would be to deny the account of the natural concept of color as expounded here. Instead, it is held, it is part of the way color terms operate in the language, that it is understood that colors may well turn out to be hidden essences. The other response involves not challenging the account of the natural concept but insisting instead that it needs to be revised or reconstructed for, say, scientific purposes.

One proposal that illustrates the first type of response is the ‘functionalist’ proposal: red is the property that disposes its bearers to look red [Cohen (2001), McLaughlin (2001)] This proposal conforms to a more general approach: to hold that that the disposition to appear is not part of what colors are essentially, but it is part of the (folk) conceptualization of a certain perceiver-independent property, which is color. The folk, it is held, use the way colors appear in order to characterize a certain property, but the way objects appear is essential to the characterisation, not the property. Here we are depending on a distinction between a property and the mode of presentation (or Fregean sense) through which the property is presented (or is thought about). Accordingly, appearances would be tied to the concept of color without being part of the property of color. It would then be open to us to identify the property through some scientific means.

The second type of response is a revisionary proposal. With this response the objectivist can concede that there are no colors in the way ordinarily conceived but hold that, nevertheless, there are colors as conceived in another manner, i.e., in an objectivist manner. After all, there are not atoms as Dalton conceived them, nor oxygen as Lavoisier conceived it, nor planets as pre-Aristotelians conceived them, but still there are atoms, oxygen and planets, all the same. In other words, the objectivist can propose a revisionary concept of color as an objective property, e.g some microstructural property or a spectral reflectance or some other light-modifying feature.

The assessment of this proposal will depend on the nature of the revision recommended. It is one thing to propose the introduction of a new concept; it is another thing to propose it as a replacement for the existing concept in the spirit of eliminating it and other competing revisions. There is no reason in principle why we should not introduce a new, different concept of color, ‘physical color’ which, we may assume, takes over the causal role specified in our characterisation of color. Such a move is legitimate, but it leaves open the possibility that there is still a need for another concept, for the causal requirement was only one of the requirements for the original concept. If the new physical concept cannot service other legitimate requirements, then we need another concept to serve these purposes. One possibility is that two new concepts should emerge. As Ian Hacking has pointed out, it is plausible that the original concept of "acid" later split into two new concepts, each perfectly legitimate. Another example is the replacement of Newtonian mass by the two new concepts of mass in relativity theory. Where previously it had been assumed that there was a single essence, it is now the case that there are two essences.

Assessing the merits of any revisionary proposal will depend on examining the reasons for modifying the original concept, and on whether there is any available rival. Before considering the objectivist's revisionary proposal, let us consider the other response the objectivist can make: to reject the account offered above of the folk or natural concept. There are two forms this response can take, a simple form and a more sophisticated one. In the simple version, the way colors appear is used as a criterion for detecting the presence of the hidden essence, but it is not essential to what it is for something to be colored. After all, gold is acknowledged as having both a hidden essence and an appearance: the real essence of gold, its atomic number, plays a causal role in producing a certain golden appearance, one that is used by language-users to identify, loosely, pieces of gold. In like manner, it is argued, colors have hidden essences which play a causal role in their having the appearances they do.

As an account of how color terms operate, this view is implausible. It has the consequence that the appearance is not essential to color; that if objects were to cease to have their distinctive appearances, while retaining their reflectance-profiles, then our color vocabulary would largely remain untouched. Our summary of the color-principles, however, revealed that all of these principles either directly involve color appearances or it was the case that the way they worked was through color appearances. Without appearances, colors would not be of any interest whatever. Just as wines would cease to have interest, even to dedicated wine-growers, were they to lose their distinctive tastes, so too would colors were they to lose their appearances. There are two possibilities. One is that through genetic change, humans became incapable of seeing objects except in terms of shades of grey. So no object has the distinctive color appearances. The second situation is the same as the first, except that 40 years later, technologists have devised spectacles (or implants) that allow people once again to see objects as colored. However they cannot match appearances with reflectances. Tomatoes have become blue, skies appear red except at sunsets when they are appear blue (or sometimes greenish-blue). It seems implausible that in such circumstances color vocabulary would go with the light-dependent properties rather than with the appearance dispositional properties.

It needs to be remembered that the situation as far as colors are concerned is very different from that for gold or aluminum. As Putnam points out, though most of us identify gold through its appearance, the appearance does not constitute (part of) the essence for gold. The reason we do so is that the appearance is a trivial criterion. It is easy to imagine circumstances in which gold would lose its lustre and in any case we distinguish fools' gold from real gold. The situation is very different for colors. Unlike gold the appearance associated with colors is crucial. The important point, as far as colors are concerned, is that colored objects have characteristic appearances and that those appearances are of great interest to us. It is because we have that interest that we need a concept of dispositional color - the power to appear in characteristic ways. It is because of the way colors appear that they are important to us both biologically and socially. It is because colored bodies appear that way (i.e., the way they do) that colors perform their various functions. To tie fool's yellow with appearance and real yellow wish some microstructural property seems absurd. Of course, if we distinguish between say physical color and psychological color, then we could imagine circumstances in which two objects which had the same psychological yellow color were ones in which one object had real physical yellow, and the other fool's physical yellow.

The Complexity of Scientific Identifications

Objectivists who hold that colors have hidden objective essences customarily draw upon standard examples within science, where microstructural properties are called upon to explain why objects have certain ‘surface’ properties, e.g., solidity, solubility, temperature, elasticity, fitness, refractive power, and so on. Such examples are meant to provide models for thinking about colors, in that they offer cases in which the surface property is reduced to, or identified with, a certain microstructural property, e.g., where light is taken to be a form of electromagnetic radiation, temperature of a gas mean kinetic energy of the constituent molecules, and so on.

The logic of scientific identifications or reductions, however, is not as clear as it might be. The concept of temperature, for example, had a distinguished scientific status long before the atomic/molecular theory emerged. If temperature originally was conceptualized as ‘that property which occupied such and such a causal role’ then the way was left open to identify temperature with mean kinetic energy. It is not at all clear, however, that this was the original scientific concept of temperature. A different way of viewing the situation is to take it that the scientific reduction (or identification) of temperature to (with) kinetic energy worked as a two stage process. It first involves a replacement of the original concept by a reconstructed one, followed by a second stage in which the reconstructed concept allows for the identification of temperature with the appropriate property described within statistical mechanics.

However not every case in science in which we can explain surface properties in terms of microstructural processes and properties are ones that involve identification or reduction. Take the example of solidity. It would seem that we have discovered what the microstructural property is that provides the causal basis for solidity. It is not at all clear, however, that solidity has been reduced to or identified with, that microstructure. It all depends on what exactly the concept of solidity is and there are different models for thinking about this concept. Not all of them lend themselves to identification and reduction, and those that do not have strong claims for legitimacy.

To appreciate such models, let us consider what reduction or identification in the case of solidity requires. To explain how solidity has been reduced, we need to specify what the original concept of solidity was. There is, however, more than one candidate. Each candidate is associated with certain causal powers: relative impenetrability, stability of a certain kind, capacities to resist, and so on. There are however, different ways in which solidity might be related to these causal capacities:

1. solidity = the causal capacities and powers to . . .
2. solidity = that microstructural basis whatever it is, that is the causal basis for the causal capacities and powers, as in 1.
3. solidity = the property of having some intrinsic structure whereby the object has the capacities as in 1.

We need to distinguish account 2 from a cousin:

> 2*. solidity = that microstructural basis whatever it is, which, as it happens, is the causal basis for the causal capacities and powers, as in 1.

The difference between Models 2 and 2* rests on how the relevant causal powers are related to the microstructure. The term ‘solidity’ is understood on either model as functioning as a name for the property but they are different types of name. In model 2 the characterisation in terms of the causal powers is essential to the understanding of the name, whereas in Model 2* it is not. In the latter case, the causal capacities are used to refer to the microstructure, but any of a number of other characterizations might have served. The causal capacities might not even hold of that particular microstructure, and yet it could refer all the same. Model 2* seems to fit names such as ‘gold’ and ‘water’ -- at least as far as capacities such as appearances and tastes are concerned. Model 2 would seem to fit terms such as

'electron', 'proton', 'gravity wave', 'force', etc., and it seems more appropriate than the other for 'solidity' and 'liquidity'.

On model 2, solidity can be identified with some microstructural property. Reference to the relevant causal capacities is essential to the conceptualization of solidity but the causal capacities are not essential to solidity itself. On the other hand, with respect to Models 1 and 3, the causal powers are essential to solidity. Given that solidity is conceptualized in these ways the causal powers are essential to the property of solidity and not just to the conceptualization.

Whichever model we adopt, we can agree that solidity has been explained by reference to certain microstructures. Only on Model 2 (or 2*) has the property been reduced to, or identified with, any microstructural property. On the other models it has not. Moreover there seems no compelling reason to favour Model 2. Scientific practice does not point in favour of it, and even if it did, it would do so only after philosophical work has been done. The fact that some modern scientists, or even most of them, say things such as "we have learned that solidity is XYZ" is not decisive. Such sayings can be taken as elliptical for statements such as "we have learned that the explanatory basis (or causal grounds) for solidity is XYZ". If it turns out that there is no single microstructural basis that is the causal basis for the causal powers, then this eventuality is well handled on model 3. This model requires that there is some basis for the causal powers, not that there is a unique basis. Model 2 on the other hand, requires a unique property. The only possible way to handle the eventuality of multiple realizations, given this account, is to say that there are different kinds of solidity each with its own unique basis. Presumably, each kind of solidity is possessed by one of a limited range of objects. In the case of temperature, it would seem that the physical basis must be different for gases, as against liquids, solids, and sub-atomic processes.

Multiple realizability of states such as temperature and solidity and potentially color, might be handled by a modification of model 2. It could be that in our reconstruction, we relativize the concept so that temperature is relativized to a range of objects, being that state which, for that range of objects, plays the distinctive causal role for that property. It is plausible to say, for example, that any eye is an eye for an organism of a certain kind. In each type of organism the eye plays a similar causal role, but it is realized by different structures in each type of organism. On this way of thinking, an eye for a spider is one thing, an eye for a human another, but what makes them both eyes is the kind of causal role they play (specified in a formal, abstract way).

The lesson the example of solidity teaches us this. First, we only have reduction or identification if the original concept is of a certain type. If it is not, if it is, for example, a pure dispositional property, then we do not have reduction or identification. In such a case, we might treat the original concept as replaceable by a revised concept. The justification would be, for example, that not only would nothing important be lost by the change, but scientific practice, say, would be enhanced. It would then be possible to have replacement plus identification (or reduction). However, that would require taking the new concept to be of a certain type, e.g., as in Model 2 or 2*, rather than of a mixed type, as in Model 3. We should not assume that in general the first type is superior to the mixed type, and should expect that it sometimes is not.

Second, if it turns out that there are multiple realizations for solubility or temperature or whatever, the only kind of identification is a relativized one. Such a relativized identification is admissible, but it requires some uniting principle. In the case of solidity, the uniting principle seems to be that of having certain causal capacities and powers. What makes the relevant microstructural property count, in the proper context, as solidity, is that it occupies a certain causal role. In the case of colors such a relativized account, one relativized to observers and the way they appear, would seem to be the most appropriate account.

Objectivist And Subjectivist Accounts

Major opposition to the objectivists come from those philosophers who hold that colors are essentially mind-dependent dispositional properties: powers to appear in distinctive kinds of ways to perceivers of the right kind. Such accounts are often called ‘subjectivist’. In comparing the merits of objectivist and subjectivist accounts, it is helpful to study the examples of solidity and liquidity, for these examples provide a set of parallels for thinking about color.

In the case of solidity and liquidity, there is a range of causal capacities that historically have been thought to be constitutive of these properties. The growth of science has seen the discovery of the microstructural properties that form the causal ground of these capacities and powers (at least in broad terms). This discovery does not mean that such microstructures constitute the essences of solidity and liquidity. There are at least two ways of thinking about what solidity and liquidity are essentially. On one model, solidity is essentially the microstructural property and the description of the causal powers forms an essential part of the way the property is characterized, rather than an essential part of the property itself. There is a second way of thinking about solidity, according to which solidity is not identified withe microstructural basis even if the latter is unique. Rather the causal powers are essential to solidity, either because solidity is identified with them, or because solidity is taken to be a second order property: for something to be solid is for it to have some property which is the basis for the relevant causal powers.

As far as color is concerned, it would seem that the objectivist would need to depend on either of the last two models. For most objectivists take colors to be essentially dispositional properties, ones characterized in terms of reflectance profiles. An object's reflectance curve represents a dispositional property: a power to differentially absorb or reflect light from the range of wavelengths constituting daylight (or a standardized equivalent).

It would seem, therefore, that as far as revisionary accounts of color are concerned, the choice is between different kinds of dispositionalist accounts: objectivist and perceiver-dependent (subjectivist). On both analyses, what colors are essentially is given by a description of appropriate causal powers. In one case these causal powers are objective ones; in the other, they are special perceiver-dependent causal powers. Let us call the respective kinds of color ‘objective color’ and ‘psychological color’. In assessing these accounts as providing revisionary proposals, the important question to ask is what can be achieved by adopting the respective proposals. There is reason to think that psychological color is superior, or at least as good.

The psychological, i.e., mind-dependent property is usually presented as being a pure disposition: to call something ‘red’ is to say that it has the power to appear red to observers of the appropriate kind. A far better proposal, which can be found in the writings of Descartes and Locke, is one that presents color in terms of a mixed disposition:

> *x* is red = *x* has some feature by virtue of which x appears red, . . .

This concept has all the advantages of the objectivist concept, and added virtues of its own. It allows for multiple realizations of the disposition, and hence of the color. It does not require that for each color there is a unique physical basis. Second, by placing emphasis on appearances, it provides the means to unite the various kinds of color: surface color, volume-color, aperture color, illumination-color, etc. And finally, it can perform the one function that the physical concept does very well: it shows how colors can have a causal role in relation to the perception of color, and the social roles played by colors.

That the mixed dispositionalist account readily solves the problem of multiple realizations is obvious. It is one of the central advantages of the psychological account, however, that it both provides a connecting link between all the various kinds of color: surface color, volume-color, aperture color, illumination-color, etc., in that it unites them all as colors while at the same time it makes intelligible their differences. For each of these colors, there is a distinct mode of appearance. For each mode of appearance, colors can be organized into systematic 3-dimension color arrays. And for each array, hue is one of the dimensions: colors can be ordered with respect to how close they are to red, green, yellow and blue. There are, however, important differences. For aperture colors, the other dimensions are saturation and lightness. for surface colors, they are chroma and value, or chromaticness and blackness/whiteness. As well, the greens, blues, yellows, etc of surfaces are different types of green, blue, yellow, etc from those of films _ but they are greens, blues, yellows, etc, for all that. It is through characterising surfaces, films, illumination-sources, and so on, as providing appearances that sense can readily be made of the range of similarities and differences between the various kinds of color. The point of having a dispositional concept framed in terms of the way things appear is that it helps provide principles of unity and diversity for the available range of color systems.

Finally the mixed dispositional concept can perform the same function that the objectivist concept can serve: it can be used to show how colors are causally relevant to the perception of color. The mixed dispositional concept retains the emphasis on red objects having the right kind of power, but it allows that the object, in having that power, has some physical feature (which may be different in different objects) which is the basis for that power. Clearly, on this analysis, the underlying physical feature has all the causal powers one could wish. The mixed dispositional analysis combines this with the advantage of keeping colors tied to the way they appear.

In addition, there is reason to think that colored objects appear is an essential part of the range of conceptual practices. The point here is that while reflectances are causally relevant, as for that matter are microstructures, so too are appearances. In the case of color there is a deeply entrenched set of activities and practices central to which is the operation of causal powers to appear, i.e., powers to cause perception

of objects as red, blue, etc. These causal powers are also central to the field of color science. Given this twofold fact, then if we are considering a revisionary concept of color, then, by analogy with solidity, there is good reason to propose a dispositionalist concept of color, for which the power to appear in a way distinctive for individual colors is essential.

The important point, as far as colors are concerned, is that colored objects have characteristic appearances and that those appearances are of great interest to us. It is because we have that interest that there is point to having a concept of dispositional color - the power to appear in characteristic ways. It is because of the way colors appear that they are important to us both biologically and socially. It is because colors have a characteristic appearance that: the colors can be ordered systematically in color arrays; they have emotional effects; principles of harmony and contrast apply; there are principles governing phenomena of color contrast. It is true that physical features both of physical objects and of retinal cells contribute causally to these phenomena, but central to all of these color principles is the way color appears.

At this stage, an objectivist might argue that there is a more fundamental causal power, one associated with reflectance curves, and for this reason it would be preferable to adopt, as a revisionary proposal, a concept of color whereby this more fundamental causal power is essential. If these two proposals are seen as competing theories, it is not clear that one is preferable to the other. Moreover it is not clear why we could not adopt both proposals and have two concepts of color, just as in the case of the geometrical property, size, we have two concepts: absolute (intrinsic) size, and angular size. That this ecumenical solution represents a viable option receives support from the consideration that if we are thinking of the proposal for the objectivist concept we have at least two proposals: one framed in terms of intrinsic microstructural properties, and one framed in terms of dispositional light-related properties. Again rather that having to choose between them, we could adopt both proposals and admit that there are different kinds of color.

In conclusion, therefore, it would appear that in so far as the objectivist is offering us a reconstruction of our original concept of color, there is reason to think that a dispositional analysis would provide a construction that is at least as good. There is strong reason, however, to think that an ecumenical solution to the problems of color can be found: that there is a place for different concepts of color, and with them different essences.

Objectivism: Problems and Solutions

It has been argued that there is room for both objectivist and psychological concepts of color, even though those providing analyses built on these concepts commonly see them as competitors. Properly interpreted, these accounts do not have to be seen as rivals. This claim can receives further support from consideration of two very different objectivist accounts, one by Jackson and Pargetter (1987), the other by David Hilbert (1987). Their respective solutions to some of the problems facing objectivism illustrate how each provides an objectivist concept of color that fits comfortably with a psychological concept, as well as with each other.

Jackson and Pargetter, who claim that each color can be identified with a physical property, have the explicit aim of overcoming the problem of multiple realizations. They concede that there is no single physical feature that is the basis for each color say, blue, but maintain that this does not matter. Blue is identified with a different physical property on different occasions, depending on what kind of physical object has it. This means relativizing the concept of color, to kinds of objects and circumstances. In principle there is no reason why there should not be a concept of physical color, in the way described by Jackson and Pargetter. The issue though is that we need some way to unify the various properties so as to bring them under the umbrella of color, and on the face of it, the psychological concept seems necessary.

The point is a general one. The objectivist who attempts to identify the objective essence for color must relate that essence to the way colors appear. Given that the criteria used by competent color perceivers to identify colors, depend on the appearances, it is necessary for the objectivist to spell out the nature of this relation. For the subjectivist the appearances constitute (part of) what the essence is. for the objectivist the appearance picks out the essence which is independent of the appearance.

In determining the right objectivist candidate, our aim is not simply to show how color vision enables, say, the observer to distinguish objects with different spectral reflectance characteristics. Rather we need to explain why one reflectance profile deserves to be classified as blue, and likewise why other profiles are related to similar and differing colors. Consequently to identify one reflectance profile as that corresponding to unique green, we need to be able to specify standard conditions and normal observers. As Hardin has persuasively pointed out, this cannot be done except in a highly arbitrary way. Not only is there a minority of color perceivers who are anomalous (only slightly, but appreciably so) with respect to normal observers, but there is a considerable statistical spread even within the group of normal observers. The reflectance profile for unique green will differ for different members of the "normal group". One can decide, of course, on a standard and fix one reflectance profile as green, but the procedure is highly arbitrary. As we have seen, there are few interesting causal powers associated with colors apart from the way objects affect perceivers. There is an alternative, however, and that is to tie color to appearance and, in consequence, relativize color to observers, with as much freedom or restriction, according to context, as is required. The most natural way to relativize color is through a dispositional concept that ties color to the way it appears to observers of the right kind. Jackson's concept of physical color would need to be supplemented by the dispositional concept. The admissibility of such a concept would not mean that the dispositional concept ought to be eliminated.

A novel twist to the objectivist program has been provided by David Hilbert (1987), with his account known as ‘Anthropocentric Realism’. It provides a solution to the multiple realizations problem but one that still seems to supplement the psychological concept, and not to dispense with it. On this view, colors are identified with spectral reflectances, at least surface colors are. A distinction is drawn between this kind of color and anthropocentric color. Individual anthropocentric colors are associated with groups of spectral reflectances. Color perception and color language ‘give us anthropocentrically defined kinds of colors and not colors themselves’. [Hilbert (1987) p. 27.] Terms such as ‘red’, ‘blue’, ‘yellow’, etc are associated with anthropocentric colors. To be red, for example, is to have a reflectance that falls within a particular class of reflectances. These classes, in general, are highly anthropocentric, sharing few interesting causal powers, and being of little consequence, apart from how they connect with the

peculiarities that underlie human color vision. The principle of grouping is that a given perceived color is associated with ‘a triple of integrated reflectances’. This association is based on the fact that human color vision depends on the use of ‘three types of broad band sensors’, i.e., the three types of light-sensitive receptors [Hilbert (1987) p. 111]

Colors, on this view, are both objective and anthropocentric. This would help explain why there is a color science and no science of color. It can also be readily modified so as to handle that problem whose resolution seems to require the relativization of color to kinds of observers. Once the concept of anthropocentric color is in place, it can be relativized, if necessary, to groups of observers.

It is Hilbert's claim that with this analysis, many of the ‘common-sense claims’ about color can be preserved, e.g., that orange is more similar to red than it is to blue. The point is that the triples of integrated reflectances can be taken as co-ordinates in a three-dimensional space, thus defining a color space. Similar colors will be located at adjacent points in this space. It is claimed that the right interpretation of statements of color similarity and dissimilarity is in terms of statements about relative location in color space.

It is with this claim that scepticism will most naturally arise. On the face of it, there is a certain qualitative character to ostensively defined color space, e.g as expressed in the Munsell or Swedish Natural color systems, that is not captured by the triple-reflectance color space. One measure of this fact is that changes along the dimensions of brightness and saturation have a different character from changes of hue from unique green to unique yellow to red to blue. Changes in Hilbert's color space don't seem to be of the right kind _ which of course is not to deny that they may not contribute to a causal explanation for why the psychological color spaces have the character that they do.

To conclude: the existence of the various problems facing the objectivist proposals do not demonstrate that the objectivist concepts are not viable. The solutions offered, however, cast doubt on the claim that objectivist concepts stand in no need of supplementary psychological concepts of color.

An Ecological View of Color

There is another theory of colors which has something in common with the illusion theory, in that it rejects objectivist accounts, but which is crucially different. It is the theory defended by Evan Thompson, the Ecological View of Colors, and is designed to be consonant with J.J.Gibson's views on perception. On this account, colors are taken to be dependent, in part, on the perceiver and so are not intrinsic properties of a perceiver-independent world. This account is not the same as an illusion theory. Being colored, instead, is construed as a relational property of the environment, connecting the environment with the perceiving animal. In the case of the color of physical surfaces, "being colored corresponds to the surface spectral reflectance as visually perceived by the animal". [Thompson (1995) Ch. 5, pp. 242-50.]

In more detail this account is spelled out in the following way: "being colored a particular determinate color or shade is equivalent to having a particular spectral reflectance, illuminance, or emittance that

looks that color to a particular perceiver in specific viewing conditions" [p.245]. Thompson insists that this account is to be distinguished from both a Lockean dispositionalist account and an illusion theory of colors. It is difficult to see, however, how he can maintain this stand. For one thing, he concedes that we see colors as perceiver-independent properties of things while maintaining that colors are perceiver-dependent properties. His answer to this difficulty, i.e., to why this is not a form of the illusion theory, is that on the ecological view it is not possible to perceive color as relational. That is, the relational nature of color does not allow the perceiver to perceive colors as relational. But this answer is not an answer to the question posed. What it explains is why one should not be surprised to find that, on the ecological view, that colors are experienced as perceiver-independent properties. But this is to admit that the way colors are represented in experience is not the way they are. The illusion theory denies that objects have the property (the color) they are represented as having. It need not deny that it is possible to formulate another concept of color that objects do satisfy. What it insists upon is that there is a need for the concept of color in the illusory sense.

A Pluralist Framework

If analysis of the natural concept of color leads to an illusion theory, or to the theory of colors as virtual properties, we still need to develop an account that prescribes how we should, in the future, think about color, at least in general terms. For practical purposes, it does not matter at all that colors are virtual properties. For these purposes, it is sufficient if "it is as if there are colors"; i.e, these purposes are served equally as well if objects appear to be colored. They do not need to be really colored.

There are other, more theoretical purposes for which we need to develop a more comprehensive account of color, one that specifies other concepts of color. The best such account is one that sets out a pluralist framework, one that allows for a variety of different concepts of color, including objectivist and psychological concepts, and arguably, ecological and phenomenal concepts. Moreover, such a framework does not require us to reject the natural or folk concept.

That there is scope for more than one concept of color should not be surprising. The natural concept of color is intended to serve a range of purposes. We find, though, that nothing exists that satisfies all the requirements. However, all is not lost. It is possible to develop a new set of color concepts that as a whole serves all or most of the previous purposes. None of them taken singly serves all, but each serves some. It is built into the natural or folk concept that colors have, broadly speaking, two major roles: (i) colors have a causal role to play in color perception; (ii) colors serve a variety of epistemological, aesthetic and emotional purposes. Colors serve the latter set of purposes through the way colors appear. Once it is recognized that colors, as specified by the traditional concept, are virtual properties and that there is no property that serves all the functions relevant to that concept, the way is open to recognize two new concepts of color: dispositional, psychological color, to take over and consolidate the role served by the appearance, and physical color, to take over the causal role. Moreover, once it is revealed that the cause of color perception are complex, it is open for us to see the point of having several physical or objectivist concepts of color, one framed in terms of microstructural properties, the other in terms of light-related properties.

To argue in this way for the place of a number of concepts of color, and for the possibility of an objectivist concept, to supplement other concepts of color, is to argue for a pluralist framework for colors. This framework has the advantage of allowing a place for an objective concept of color, while not making it mandatory. Whether or not there is any point in having an objective concept, there is, as we have seen, a need for a dispositional concept, one tied to the appearance of color. The dispositional concept is a crucial part of the pluralist framework.

But once we become enlightened by accepting the theory of virtual colors, how should we then think of the dispositional concept? What exactly does the exercise of the disposition consist in? What exactly is the content of the dispositional concept? The right answer is that there are two parts to the dispositionalist concept. One part refers to the way objects appear, and the other to the feature, whatever it is, which is the causal basis for the appearance. That is, the disposition is not pure but ‘mixed’. BlueD objects are objects that have some feature by virtue of which they look as if they are blue, i.e., blue in the intrinsic sense, i.e., blue in the virtual-color sense. To say that this sense of color is the virtual-color sense is not to say that colors are ordinarily conceived of as virtual. It is to say that the properties colors are conceived of as being are virtual. The content of the dispositional concept thus presupposes the virtual-color concept. This means that there is point in retaining this concept, even when we come to know that no objects have the property. The fact that I do not believe that this property of intrinsic blueness is ever instantiated does not mean that I should give up the concept, any more than disbelievers in Satan should give up the concept of satanic.

In this state of theoretical sophistication, my use of the natural concept to describe things requires me to adopt the naive attitude to color or, preferably, the engaged attitude typical of the playgoer who, at the theatre, suspends his belief that ‘it is all a pack of lies’. Of course as philosophers, we need to understand why we have this virtual-color concept and what role it plays, and how it works. But none of that stops me from continuing to employ the virtual-color concept, whether as scientist, artist, consumer, town-planner, interior decorator or philosopher. As for serving functions such as being signs or as being aesthetically or emotionally significant, virtual colors are as good as real colors.

There is no need therefore to jettison the natural concept. Realizing however that the color properties are virtual properties means that, for our understanding of how such a concept should apply and why it is so beneficial. Part of this understanding is provided by the explanation for why we have the natural concept that we do. The explanation for why the natural concept is beneficial is that the purposes served by the concepts are equally well served if objects merely appear to be colored and are not actually colored.

Colors as Phenomenal Qualities

Given the virtual colors theory, there is a further problem that needs to be resolved: to explain how it is that the natural concept takes the form that it does, and in particular how it contains the basis for the structure that underpins the color systems for ordering colors. One of the characteristics of the color properties captured in the natural concept is that colors are the sorts of properties among which a set of

internal relationships hold. That is, colors as a block, have a qualitative, sensuous character that enables objects having them to be systematically ordered and arranged. There are no physical features that have this character. One explanation for why this character is part of the virtual color property is that our sensory representations (or the elements/aspects in our visual experiences) have the qualitative character. It is because the sensory representations have the qualitative character that they do, that they represent physical objects as having the qualitative character in question.

The way that the phenomenal concept, i.e., the concept of color as a phenomenal property is introduced is that it serves to explain why the natural concept of color has the character that it does. When we have color experiences, typically we form sensory representations of the world. These representations represent objects in the physical world as having (virtual) colors, and they do so because the representations have the character implicit in three-dimensional color arrays. The representations do not have virtual colors (they have the right kind of structure, but they do not have the right causal powers), but they represent physical objects as having those colors. Sensory representations, in other words, have the phenomenological character that physical objects might have had but do not.

The qualitative character that the sensory representations have is sensory and phenomenal in the strongest sense. The character is ontologically subjective. In visual experience we experience the sensory color qualities as being in a public three dimensional space. That is, our experiences, and our sensory representations, represent the color qualities as being on the surfaces of physical objects, or as otherwise located in physical space. Contrary to what some philosophers believe, there is no more problem in experiencing phenomenal qualities in such a way than there is in feeling a pain in a foot or an elbow. In the case of pains, the phenomenal quality is felt on a bodily location, e.g., behind the eye, or in an elbow, etc. It needs to be said that although our sensory representations have phenomenal color qualities, which we are aware of, we are not aware of them as phenomenal qualities, that is, as phenomenal qualities of physical objects. We use the sensory representations as signs for physical objects, but we are not aware of the sign as a sign. It needs to be stressed that this account does not require colors, either phenomenal or virtual, to be projected into space. Just as they represent objects as having virtual colors, so they represent objects as having spatial properties (and relations) through themselves having phenomenal spatial properties.

Conclusion

It has been argued an adequate account of color must, in the first place, provide an account of the folk concept or natural concept of color. Such an account, there is reason to believe, is an illusion theory of color. Supposing that colors, as we normally think of them, are virtual properties, we are faced with the question of how, if at all, should we adjust our ideas in thinking of colors. If normally our perception of color involves ‘false consciousness’, what is the right way to think of colors? The answer to that is that for many purposes we should continue to think of them in the same way as we always did. In the case of color, unlike other cases, false consciousness should be a cause for celebration.

Although for most practical purposes, it does not matter that colors are virtual properties, there are more

theoretical purposes, however, for which we need to develop a more comprehensive account, a pluralist account of color. The different elements of the natural concept of color reflect different functions that colors are meant to play. Given these different functions and the fact that there is no property that satisfies all of them, it is open to us to develop a pluralist framework in which different concepts of color take over different functions. This pluralist framework makes room for the introduction of objectivist concepts of color, but such concepts need to stand beside a dispositionalist concept which makes reference to the way colors appear to perceivers, and arguably, with the latter, a phenomenal concept. It is such a framework that is necessary to give an adequate account of the rich epistemological and socially important roles that colors play.

Realism

The nature and plausibility of realism is one of the most hotly debated issues in contemporary metaphysics, perhaps even the most hotly debated issue in contemporary philosophy. The question of the nature and plausibility of realism arises with respect to a large number of subject matters, including ethics, aesthetics, causation, modality, science, mathematics, semantics, and the everyday world of macroscopic material objects and their properties. Although it would be possible to accept (or reject) realism across the board, it is more common for philosophers to be selectively realist or non-realist about various topics: thus it would be perfectly possible to be a realist about the everyday world of macroscopic objects and their properties, but a non-realist about aesthetic and moral value. In addition, it is misleading to think that there is a straightforward and clear-cut choice between being a realist and a non-realist about a particular subject matter. It is rather the case that one can be more-or-less realist about a particular subject matter. Also, there are many different forms that realism and non-realism can take.

The question of the nature and plausibility of realism is so controversial that no brief account of it will satisfy all those with a stake in the debates between realists and non-realists. This article offers a broad brush characterisation of realism, and then fills out some of the detail by looking at a few canonical examples of opposition to realism. The discussion of forms of opposition to realism is far from exhaustive and is designed only to illustrate a few paradigm examples of the form such opposition can take.

There are two general aspects to realism, illustrated by looking at realism about the everyday world of macroscopic objects and their properties. First, there is a claim about *existence*. Tables, rocks, the moon, and so on, all exist, as do the following facts: the table's being square, the rock's being made of granite, and the moon's being spherical and yellow. The second aspect of realism about the everyday world of macroscopic objects and their properties concerns *independence*. The fact that the moon exists and is spherical is independent of anything anyone happens to say or think about the matter. Likewise, although there is a clear sense in which the table's being square is dependent on us (it was designed and constructed by human beings after all), this is not the type of dependence that the realist wishes to deny. The realist wishes to claim that apart from the mundane sort of empirical dependence of objects and their properties familiar to us from everyday life, there is no *further* sense in which everyday objects and their properties can be said to be dependent on anyone's linguistic practices, conceptual schemes, or whatever.

In general, where the distinctive objects of a subject-matter are *a*, *b*, *c*, … , and the distinctive properties are …*is F*, …*is G*, …*is H* and so on, realism about that subject matter will typically take the form of a claim like the following:

> **Generic Realism**:
> *a*, *b*, and *c* and so on exist, and the fact that they exist and have properties such as *F-ness*, *G-ness*, and *H-ness* is (apart from mundane empirical dependencies of the sort sometimes encountered in everyday life) independent of anyone's beliefs, linguistic practices, conceptual schemes, and so on.

Non-realism can take many forms, depending on whether or not it is the existence or independence dimension of realism that is questioned or rejected. The forms of non-realism can vary dramatically from subject-matter to subject-matter, but error-theories, non-cognitivism, instrumentalism, nominalism, certain styles of reductionism, and eliminativism typically reject realism by rejecting the existence dimension, while idealism, subjectivism, and anti-realism typically concede the existence dimension but reject the independence dimension. Philosophers who subscribe to quietism deny that there can be such a thing as substantial metaphysical debate between realists and their non-realist opponents.

---

1. Preliminaries

Three preliminary comments are needed. Firstly, there has been a great deal of debate in recent philosophy about the relationship between realism, construed as a metaphysical doctrine, and doctrines in the theory of meaning and philosophy of language concerning the nature of truth and its role in accounts of linguistic understanding (see Dummett 1978 and Devitt 1991a for radically different views on the issue). Independent of the issue about the relationship between metaphysics and the theory of meaning, the well-known disquotational properties of the truth-predicate allow claims about objects, properties, and facts to be framed as claims about the truth of sentences. Since:

> (1) ‘The moon is spherical’ is true if and only if the moon is spherical.

The claim that the moon exists and is spherical can be framed independently of anyone's beliefs, linguistic practices and conceptual schemes, as the claim that the sentences ‘The moon exists’ and ‘The moon is spherical’ are true independently of anyone's beliefs, linguistic practices, conceptual schemes and so on. As Devitt points out (1991b: 46) availing oneself of this way of talking does not entail that one sees the metaphysical issue of realism as ‘really’ a semantic issue about the nature of truth (if it did, any question about any subject matter would turn out to be ‘really’ a semantic issue).

Secondly, although in introducing the notion of realism above mention is made of objects, properties, and facts, no theoretical weight is attached to the notion of a ‘fact’, or the notions of ‘object’ and ‘property’. To say that it is a fact that the moon is spherical is just to say that the object, the moon, instantiates the property of being spherical, which is just to say that the moon is spherical. There are substantial metaphysical issues about the nature of facts, objects, and properties, and the relationships between them (see Mellor and Oliver 1997 and Lowe 2002, part IV), but these are not of concern here.

Thirdly, as stated above, Generic Realism about the mental or the intentional would strictly speaking appear to be ruled out *ab initio*, since clearly Jones' believing that Cardiff is in Wales is not independent of facts about belief: trivially, it is dependent on the fact that Jones believes that Cardiff is in Wales. However, such trivial dependencies are not what are at issue in debates between realists and non-realists about the mental and the intentional. A non-realist who objected to the independence dimension of realism about the mental would claim that Jones' believing that Cardiff is in Wales depends in some *non-trivial* sense on facts about beliefs, etc.

2. Against the Existence Dimension (I): Error-Theory and Arithmetic

There are at least two distinct ways in which a non-realist can reject the existence dimension of realism about a particular subject matter. The first of these rejects the existence dimension by rejecting the claim that the distinctive objects of that subject-matter exist, while the second admits that those objects exist but denies that they instantiate any of the properties distinctive of that subject-matter. Non-realism of the first kind can be illustrated via Hartry Field's error-theoretic account of arithmetic, and non-realism of the second kind via J.L. Mackie's error-theoretic account of morals. This will show how realism about a subject-matter can be questioned on both epistemological and metaphysical grounds.

According to a *platonist* about arithmetic, the truth of the sentence ‘7 is prime’ entails the existence of an *abstract object*, the number 7. This object is abstract because it has no spatial or temporal location, and is causally inert. A *platonic realist* about arithmetic will say that the number 7 exists and instantiates the property of being prime independently of anyone's beliefs, linguistic practices, conceptual schemes, and so on. A certain kind of nominalist rejects the existence claim which the platonic realist makes: there are no abstract objects, so sentences such as ‘7 is prime’ are *false* (hence the name ‘error-theory’). Platonists divide on their account of the epistemology of arithmetic: some claim that our knowledge of arithmetical fact proceeds by way of some quasi-perceptual encounter with the abstract realm (Gödel 1983), while

others have attempted to resuscitate a qualified form of Frege's *logicist* project of grounding knowledge of arithmetical fact in knowledge of logic (Wright 1983, Hale 1987, Hale and Wright 2001).

The main arguments against platonic realism turn on the idea that the platonist position precludes a satisfactory epistemology of arithmetic. For the classic exposition of the doubt that platonism can square its claims to accommodate knowledge of arithmetical truth with its conception of the subject matter of arithmetic as causally inert, see Benacerraf (1973). Benacerraf argued that platonism faces difficulties in squaring its conception of the subject-matter of arithmetic with a general causal constraint on knowledge (roughly, that a subject can be said to know that *P* only if she stands in some causal relation to the subject matter of *P*). In response, platonists have attacked the idea that a plausible causal constraint on ascriptions of knowledge can be formulated (Wright 1983 Ch.2, Hale 1987 Ch.4). In response, Hartry Field, on the side of the anti-platonists, has developed a new variant of Benacerraf's epistemological challenge which does not depend for its force on maintaining a generalised causal constraint on ascriptions of knowledge. Rather, Field's new epistemological challenge to platonism arises from his reasonable observation that ‘we should view with suspicion any claim to know facts about a certain domain if we believe it impossible to explain the reliability of our beliefs about that domain’ (Field 1989: 232-3). Field's challenge to the platonist is to offer an account of what such a platonist should regard as a datum—i.e. that when ‘*p*’ is replaced by a mathematical sentence, the schema (2) holds in most instances :

> (2) If mathematicians accept ‘*p*’ then *p*. (1989: 230)

Field's point is not simply, echoing Benacerraf, that no causal account of reliability will be available to the platonist, and therefore to the platonic realist. Rather, Field conceives what is potentially a far more powerful challenge to platonic realism when he suggests that not only has the platonic realist no recourse to any explanation of reliability that is causal in character, but that she has no recourse to any explanation that is non-causal in character either. He writes:

> (T)here seems prima facie to be a difficulty in principle in explaining the regularity. The problem arises in part from the fact that mathematical entities as the [platonic realist] conceives them, do not causally interact with mathematicians, or indeed with anything else. This means we cannot explain the mathematicians beliefs and utterances on the basis of the mathematical facts being causally involved in the production of those beliefs and utterances; or on the basis of the beliefs or utterances causally producing the mathematical facts; or on the basis of some common cause producing both. Perhaps then some sort of non-causal explanation of the correlation is possible? Perhaps; but it is very hard to see what this supposed non-causal explanation could be. Recall that on the usual platonist picture [i.e. platonic realism], mathematical objects are supposed to be mind- and language-independent; they are supposed to bear no spatiotemporal relations to anything, etc. The problem is that the claims that the [platonic realist] makes about mathematical objects appears to rule out any reasonable strategy for explaining the systematic correlation in question. (1989: 230-1)

This suggests the following dilemma for the platonic realist:

i. Platonic realism is committed to the existence of acausal objects and to the claim that these objects, and facts about them, are independent of anyone's beliefs, linguistic practices, conceptual schemes, and so on (in short to the claim that these objects, and facts about them, are language- and mind-independent).
ii. Any causal explanation of reliability is incompatible with the acausality of mathematical objects.
iii. Any non-causal explanation of reliability is incompatible with the language- and mind-independence of mathematical objects.
iv. Any explanation of reliability must be causal or non-causal.
v. There is no explanation of reliability that is compatible with both the acausality and language- and mind-independence of mathematical objects.

Therefore,

vi. There is no explanation of reliability that is compatible with platonic realism.

Whether there is a version of platonic realism with the resources to see off Field's epistemological challenge is very much a live issue (see Hale 1994, Divers and Miller 1999).

What does Field propose as an alternative to platonic realism in arithmetic? Field's answer (1980, 1989) is that although mathematical sentences such as ‘7 is prime’ are false, the utility of mathematical theories can be explained otherwise than in terms of their truth. For Field, the utility of mathematical theories resides not in their truth but in their *conservativeness*, where a mathematical theory *S* is conservative if and only if for any nominalistically respectable statement *A* (i.e. a statement whose truth does not imply the existence of abstract objects) and any body of such statements *N*, *A* is not a consequence of the conjunction of *N* and *S* unless *A* is a consequence of *N* alone (Field 1989: 125). In short, mathematics is useful, not because it allows you to derive conclusions that you couldn't have derived from nominalistically respectable premises alone, but rather because it makes the derivation of those (nominalistically respectable) conclusions easier than it might otherwise have been. Whether or not Field's particular brand of error-theory about arithmetic is plausible is a topic of some debate, which unfortunately I cannot pursue further here (see Hale and Wright 2001).

3. Against the Existence Dimension (II): Error-Theory and Morality

According to Field's error-theory of arithmetic, the objects distinctive of arithmetic do not exist, and it is this which leads to the rejection of the existence dimension of arithmetical realism, at least as platonistically conceived (for a non-platonistic view of arithmetic which is at least potentially realist, see Benacerraf 1965; for incisive discussion, see Wright 1983, Ch.3). J. L. Mackie , on the other hand, proposes an error-theoretic account of morals, not because there are no objects or entities that could form the subject matter of ethics (it is no part of Mackie's brief to deny the existence of persons and their

actions and so on), but because it is implausible to suppose that the sorts of properties that moral properties would have to be are ever instantiated in the world (Mackie 1977, Ch.1). Like Field on arithmetic, then, Mackie's central claim about the atomic, declarative sentences of ethics (such as ‘Napoleon was evil’) is that they are systematically and uniformly false. How might one argue for such a radical-sounding thesis? The clearest way to view Mackie's argument for the error-theory is as a conjunction of a conceptual claim with an ontological claim (following Smith 1994, pp.63-66). The conceptual claim is that our concept of a moral fact is a concept of an objectively prescriptive fact, or, equivalently, that our concept of a moral property is a concept of an objectively prescriptive quality (what Mackie means by this is explained below). The ontological claim is simply that there are no objectively prescriptive facts, that objectively prescriptive properties are nowhere instantiated. The conclusion is that there is nothing in the world answering to our moral concepts, no facts or properties which render the judgements formed via those moral concepts true. Our moral judgements are all of them false. We can thus construe the error-theory as follows:

> **Conceptual Claim:** our concept of a moral fact is a concept of an objectively prescriptive fact, so that the truth of an atomic, declarative moral sentence would require the existence of objectively and categorically prescriptive facts.
>
> **Ontological Claim:** There are no objectively and categorically prescriptive facts.
>
> So,
>
> **Conclusion:** there are no moral facts; atomic, declarative moral sentences are systematically and uniformly false.

This argument is clearly valid, so the question facing those who wish to defend at least the existence dimension of realism in the case of morals is whether the premises are true.

Mackie's conceptual claim is that our concept of a moral requirement is the concept of an objectively, categorically prescriptive requirement. What does this mean? To say that moral requirements are prescriptive is to say that they tell us how we ought to act, to say that they give us reasons for acting. Thus, to say that something is morally good is to say that we ought to pursue it, that we have reason to pursue it. To say that something is morally bad is to say that we ought not to pursue it, that we have reason not to pursue it. To say that moral requirements are categorically prescriptive is to say that these reasons are categorical in the sense of Kant's categorical imperatives. The reasons for action that moral requirements furnish are not contingent upon the possession of any desires or wants on the part of the agent to whom they are addressed: I cannot release myself from the requirement imposed by the claim that torturing the innocent is wrong by citing some desire or inclination that I have. This contrasts, for example, with the requirement imposed by the claim that perpetual lateness at work is likely to result in one losing one's job: I can release myself from the requirement imposed by this claim by citing my desire to lose my job (perhaps because I find it unfulfilling, or whatever). Reasons for action which are contingent in this way on desires and inclinations are furnished by what Kant called hypothetical imperatives.

So our concept of a moral requirement is a concept of a categorically prescriptive requirement. But Mackie claims further that our concept of a moral requirement is a concept of an objectively categorically prescriptive requirement. What does it mean to say that a requirement is objective? Mackie says a lot of different-sounding things about this, and the following is by no means a comprehensive list (references are to Ch. 1 of Mackie 1977). To call a requirement objective is to say that it can be an object of knowledge (24, 31, 33), that it can be true or false (26, 33), that it can be perceived (31, 33), that it can be recognised (42), that it is prior to and independent of our preferences and choices (30, 43), that it is a source of authority external to our preferences and choices (32, 34, 43), that it is part of the fabric of the world (12), that it backs up and validates some of our preferences and choices (22), that it is capable of being simply true (30) or valid as a matter of general logic (30), that it is not constituted by our choosing or deciding to think in a certain way (30), that it is extra-mental (23), that it is something of which we can be aware (38), that it is something that can be introspected (39), that it is something that can figure as a premise in an explanatory hypothesis or inference (39), and so on. Mackie plainly does not take these to be individually necessary: facts about subatomic particles, for example, may qualify as objective in virtue of figuring in explanatory hypotheses even though they cannot be objects of perceptual acquaintance. But his intention is plain enough: these are the sorts of conditions whose satisfaction by a fact renders it objective as opposed to subjective. Mackie's conceptual claim about morality is thus that our concept of a moral requirement is a concept of a fact which is objective in at least some of the senses just listed, while his ontological claim will be that the world does not contain any facts which are both candidates for being moral facts and yet which play even some of the roles distinctive of objective facts.

How plausible is Mackie's conceptual claim? This issue cannot be discussed in detail here, except to note that while it seems plausible to claim that *if* our concept of a moral fact is a concept of a reason for action *then* that concept must be a concept of a categorical reason for action, it is not so clear why we have to say that our concept of a moral fact is a concept of a reason for action at all. If we deny this, we can concede the conditional claim whilst resisting Mackie's conceptual claim. One way to do this would be to question the assumption, implicit in the exposition of Mackie's argument for the conceptual claim above, that an ‘ought’-statement that binds an agent A provides that agent with a reason for action. For an example of a version of moral realism that attempts to block Mackie's conceptual claim in this way, see Railton (1986). For defence of Mackie's conceptual claim, see Smith (1994), Ch.3. For exposition and critical discussion, see Miller (2003a), Ch.9.

What is Mackie's argument for his ontological claim? This is set out in his ‘argument from queerness’ (Mackie has another argument, the ‘argument from relativity’(1977: 36-38), but this argument cannot be discussed here).The argument from queerness has both metaphysical and epistemological components. The metaphysical problem with objective values concerns ‘the metaphysical peculiarity of the supposed objective values, in that they would have to be intrinsically action-guiding and motivating’(49). The epistemological problem concerns ‘the difficulty of accounting for our knowledge of value entities or features and of their links with the features on which they would be consequential’(49). Let's look at each type of worry more closely in turn.

Expounding the metaphysical part of the argument from queerness, Mackie writes: “If there were

objective values, then they would be entities or relations of a very strange sort, utterly different from anything else in the universe."(38) What is so strange about them? Mackie says that Plato's Forms (and for that matter, Moore's non-natural qualities) give us a 'dramatic picture' of what objective values would be, if there were any:

> The Form of the Good is such that knowledge of it provides the knower with both a direction and an overriding motive; something's being good both tells the person who knows this to pursue it and makes him pursue it. An objective good would be sought by anyone who was acquainted with it, not because of any contingent fact that this person, or every person, is so constituted that he desires this end, but just because the end has to-be-pursuedness somehow built into it. Similarly, if there were objective principles of right and wrong, any wrong (possible) course of action would have not-to-be-doneness somehow built into it. Or we should have something like Clarke's necessary relations of fitness between situations and actions, so that a situation would have a demand for such-and-such an action somehow built into it (40).

The obtaining of a moral states of affairs would be the obtaining of a situation 'with a demand for such and such an action somehow built into it'; the states of affairs which we find in the world do not have such demands built into them, they are 'normatively inert', as it were. Thus, the world contains no moral states of affairs, situations which consist in the instantiation of a moral quality.

Mackie now backs up this metaphysical argument with an epistemological argument:

> If we were aware [of objective values], it would have to be by some special faculty of moral perception or intuition, utterly different from our ways of knowing everything else. These points were recognised by Moore when he spoke of non-natural qualities, and by the intuitionists in their talk about a faculty of moral intuition. Intuitionism has long been out of favour, and it is indeed easy to point out its implausibilties. What is not so often stressed, but is more important, is that the central thesis of intuitionism is one to which any objectivist view of values is in the end committed: intuitionism merely makes unpalatably plain what other forms of objectivism wrap up (38).

In short, our ordinary conceptions of how we might come into cognitive contact with states of affairs, and thereby acquire knowledge of them, cannot cope with the idea that the states of affairs are objective values. So we are forced to expand that ordinary conception to include forms of moral perception and intuition. But these are completely unexplanatory: they are really just placeholders for our capacity to form correct moral judgements (the reader should here hear an echo of the complaints Benecerraf and Field raise against arithmetical platonism).

Evaluating the argument from queerness is well outwith the scope of the present entry. While Railton's version of moral realism attempts to block Mackie's overall argument by conceding his ontological claim whilst rejecting his conceptual claim, other versions of moral realism agree with Mackie's conceptual claim but reject his ontological claim. Examples of the latter version, and attempts to provide the owed

response to the argument from queerness, can be found in Smith (1994), Ch.6, and McDowell (1998a), Chs 4-10 .

There are two main ways in which one might respond to Mackie's argument for the error-theory: directly, via contesting one of its premises or inferences, or indirectly, pointing to some internal tension within the error-theory itself. Some possible direct responses have already mentioned, responses which reject either the conceptual or ontological claims that feature as premises in Mackie's argument for the error-theory. An indirect argument against the error-theory has been developed in recent writings by Crispin Wright (this argument is intended to apply also to Field's error-theory of arithmetic).

Mackie claims that the error-theory of moral judgement is a second-order theory, which does not necessarily have implications for the first order practice of making moral judgements (1977: 16). Wright's argument against the error-theory takes off with the forceful presentation of the opposing suspicion:

> The great discomfort with [Mackie's] view is that, unless more is said, it simply relegates moral discourse to bad faith. Whatever we may once have thought, as soon as philosophy has taught us that the world is unsuited to confer truth on any of our claims about what is right, or wrong, or obligatory, etc., the reasonable response ought surely to be to forgo the right to making any such claims …. If it is of the essence of moral judgement to aim at the truth, and if philosophy teaches us that there is no moral truth to hit, how are we supposed to take ourselves seriously in thinking the way we do about any issue which we regard as of major moral importance? (1996: 2; see also 1992: 9).

Wright realises that the error-theorist is likely to have a story to tell about the point of moral discourse, about "some norm of appraisal besides truth, at which its statements can be seen as aimed, and which they can satisfy."(1996: 2) And Mackie has such a story: the point of moral discourse is—to simplify—to secure the benefits of social co-operation (1973: chapter 5 passim; note that this is the analogue in Mackie's theory of Field's notion of the conservativeness of mathematical theories). Suppose we can extract from this story some subsidiary norm distinct from truth, which governs the practice of forming moral judgements. Then, for example, 'Honesty is good' and 'Dishonesty is good', although both false, will not be on a par in point of their contribution to the satisfaction of the subsidiary norm: if accepted widely enough, the former will presumably facilitate the satisfaction of the subsidiary norm, while the latter, if accepted widely enough, will frustrate it. Wright questions whether Mackie's moral sceptic can plausibly combine such a story about the benefits of the practice of moral judgement with the central negative claim of the error-theory:

> [I]f, among the welter of falsehoods which we enunciate in moral discourse, there is a good distinction to be drawn between those which are acceptable in the light of some such subsidiary norm and those which are not—a distinction which actually informs ordinary discussion and criticism of moral claims—then why insist on construing *truth* for moral discourse in terms which motivate a charge of global error, rather than explicate it in terms of the satisfaction of the putative subsidiary norm, whatever it is? The question may have a good answer. The error-theorist may be able to argue that the superstition that he finds in

> ordinary moral thought goes too deep to permit of any construction of *moral* truth which avoids it to be acceptable as an account of moral truth. But I do not know of promising argument in that direction (1996: 3; see also 1992: 10).

Wright thus argues that even if we concede to the error-theorist that his original scepticism about moral truth is well-founded, the error-theorist's own positive proposal will be inherently unstable. For an attempt to respond to Wright's argument, on behalf of the error-theorist, see Miller 2002.

4. Reductionism and Non-Reductionism

Although some commentators (e.g. Pettit 1991) require that a realistic view of a subject matter be non-reductionist about the distinctive objects, properties, and facts of that subject matter, the reductionist/non-reductionist issue is really orthogonal to the various debates about realism. There are a number of reasons for this, with the reasons varying depending on the type of reduction proposed.

Suppose, first of all, that one wished to deny the existence claim which is a component of platonic realism about arithmetic. One way to do this would be to propose an *analytic reduction* of talk seemingly involving abstract entities to talk concerning only concrete entities. This can be illustrated by considering a language the truth of whose sentences seemingly entails the existence of a type of abstract object, directions. Suppose there is a first order language L, containing a range of proper names ‘*a*’, ‘*b*’, ‘*c*’, and so on, where these denote straight lines conceived as concrete inscriptions. There are also predicates and relations defined on straight lines, including ‘ … is parallel to …’. ‘*D*( )’ is a singular term forming operator on lines, so that inserting the name of a concrete line, as in ‘*D*(*a*)’, produces a singular term standing for an abstract object, the direction of *a*. A number of contextual definitions are now introduced:

> (A) ‘$D(a) = D(b)$’ is true if and only if *a* is parallel to *b*.
>
> (B) ‘$\Pi D(x)$’ is true if and only if ‘Fx’ is true, where ‘… is parallel to …’ is a congruence for ‘*F*( )’.
>
> (To say that ‘… is parallel to …’ is a congruence for ‘*F*( )’ is to say that if *a* is parallel to *b* and *Fa*, then it follows that *Fb*).
>
> (C) ‘$(\exists x)\Pi x$’ is true if and only if ‘$(\exists x)Fx$’ is true, where ‘Π’ and ‘*F*’ are as in (B).

According to a platonic realist, directions exist and have a nature which is independent of anyone's beliefs, linguistic practices, conceptual schemes, and so on. But doesn't the availability of (A), (B), and (C) undermine the existence claim at the heart of platonic realism? After all, (A), (B), and (C) allow us to paraphrase any sentence whose truth appears to entail the existence of abstract objects into a sentence whose truth involves only the existence of concrete inscriptions. Doesn't this show that an analytic reduction can aid someone wishing to question the existence claim involved in a particular form of

realism? There is a powerful argument, first developed by William Alston (1958), and recently resuscitated to great effect by Crispin Wright (1983, Ch.1), that suggests not. The analytic reductionist who wishes to wield the contextual definitions against the existence claim at the heart of platonic realism takes them to show that the apparent reference to abstract objects on the left-hand sides of the definitions is *merely* apparent: in fact, the truth of the relevant sentences entails only the existence of a range of concrete inscriptions. But the platonic realist can retort: what the contextual definitions show is that the apparent *lack* of reference to abstract objects on the *right-hand* sides is merely apparent. In fact, the platonic realist can say, the truth of the sentences figuring on the right-hand sides implicitly involves reference to abstract objects. If there is no way to break this deadlock the existence of the analytic reductive paraphrases will leave the existence claim at the heart of the relevant form of realism untouched. So the issue of this style of reductionism appears to be orthogonal to debates between realists and non-realists.

Can the same be said about non-analytic styles of reductionism? Again, there is no straightforward connection between the issue of reductionism and the issue of realism. The problem is that, to borrow some terminology and examples from Railton 1989, some reductions will be *vindicative* whilst others will be *eliminativist*. For example, the reduction of water to H_20 is vindicative: it vindicates our belief that there is such a thing as water, rather than overturning it. On the other hand:

> … the reduction of ‘polywater’—a peculiar form of water thought to have been observed in laboratories in the 1960's—to ordinary-water-containing-some impurities-from-improperly-washed-glassware contributed to the conclusion that there really is no such substance as polywater (1989: 161).

Thus, a non-analytic reduction may or may not have implications for the existence dimension of a realistic view of a particular subject matter. And even if the existence dimension is vindicated, there is still the further question whether the objects and properties vindicated are independent of anyone's beliefs, linguistic practices, and so on. Again, there is no straightforward relationship between the issue of reductionism and the issue of realism.

5. Against the Existence Dimension (III): Expressivism about Morals

We saw above that for the subject-matter in question the error-theorist *agrees* with the realist that the truth of the atomic, declarative sentences of that area requires the existence of the relevant type of objects, or the instantiation of the relevant sorts of properties. Although the realist and the error-theorist agree on this much, they of course disagree on the question of whether the relevant type of objects exist, or on whether the relevant sorts of properties are instantiated: the error-theorist claims that they don't, so that the atomic, declarative sentences of the area are systematically and uniformly false, the realist claims that at least in some instances the relevant objects exist or the relevant properties are instantiated, so that the atomic, declarative sentences of the area are at least in some instances true. We also saw that an error-

theory about a particular area could be motivated by epistemological worries (Field) or by a combination of epistemological and metaphysical worries (Mackie).

Another way in which the existence dimension of realism can be resisted is via expressivism about morals. Whereas the realist and the error-theorist agree that the sentences of the relevant area are *truth-apt*, apt to be assessed in terms of truth and falsity, the realist and the expressivist (alternatively non-cognitivist, projectivist) disagree about the truth-aptness of those sentences. It is a fact about English that sentences in the declarative mood ('The beer is in the fridge') are conventionally used for making assertions, and assertions are true or false depending on whether or not the fact that is asserted to obtain actually obtains. But there are other grammatical moods that are conventionally associated with different types of speech-act. For example, sentences in the imperatival mood ('Put the beer in the fridge') are conventionally used for giving orders, and sentences in the interrogative mood ('Is the beer in the fridge?') are conventionally used for asking questions. Note that we would not ordinarily think of orders or questions as even apt for assessment in terms of truth and falsity: they are not truth-apt. Now the conventions mentioned here are not exceptionless: for example, one can use sentences in the declarative mood ('My favourite drink is Belhaven 60 shilling') to give an order (for some Belhaven 60 shilling), one can use sentences in the interrogative mood ('Is the Pope a Catholic?') to make an assertion (of whatever fact was the subject of the discussion), and so on. The expressivist about a particular area will claim that the realist is misled by the syntax of the sentences of that area into thinking that they are truth-apt: she will say that this is a case where the conventional association of the declarative mood with assertoric force breaks down. 'Stealing is wrong' is no more truth-apt than 'Put the beer in the fridge': it is just that the truth-aptness of the latter is worn on its sleeve, while the lack of truth-aptness of the former is veiled by its surface syntax.

So, if moral sentences are not conventionally used for the making of assertions, what are they conventionally used for? According to one classical form of expressivism, *emotivism*, they are conventionally used for the expression of emotion, feeling, or sentiment. Thus, A.J. Ayer writes:

> If I say to someone, 'You acted wrongly in stealing that money', I am not stating anything more than if I had simply said, 'You stole that money'. In adding that this action is wrong, *I am not making any further statement about it. I am simply evincing my moral disapproval about it.* It is as if I had said, 'You stole that money', in a peculiar tone of horror, or written with the addition of some special exclamation marks. The tone, or the exclamation marks, adds nothing to the literal meaning of the sentence. *It merely serves to show that the expression of it is attended by certain feelings in the speaker* (Ayer 1946: 107, emphases added).

It follows from this that:

> If I now generalise my previous statement and say, 'Stealing money is wrong,' I produce a sentence which has no factual meaning—that is, expresses no proposition that can be either true or false (1946: 107).

Emotivism faces many problems, discussion of which is not possible here (for a survey, see Miller 2003a Ch.3). One problem that has been the bugbear of all expressivist versions of non-realism, the 'Frege-Geach Problem', is so-called because the classic modern formulation is by Peter Geach (1960), who attributes the original point to Frege.

According to emotivism, when I sincerely utter the sentence 'Murder is wrong' I am not expressing a belief or making an assertion, but rather expressing some non-cognitive sentiment or feeling, incapable of being true or false. Thus, the emotivist claims that in contexts where 'Murder is wrong' is apparently being used to assert that murder is wrong it is in fact being used to express a sentiment or feeling of disapproval towards murder. But what about contexts in which it is not even apparently the case that 'Murder is wrong' is being used to make an assertion? An example of such a sentence would be 'If murder is wrong, then getting little brother to murder people is wrong'. In the antecedent of this 'Murder is wrong' is clearly not even apparently being used to make an assertion. So what account can the emotivist give of the use of 'Murder is wrong' within 'unasserted contexts', such as the antecedent of the conditional above? Since it is not there used to express disapproval of murder, the account of its semantic function must be different from that given for the apparently straightforward assertion expressed by 'Murder is wrong'. But now there is a problem in accounting for the following apparently valid inference:

> (1) Murder is wrong.
>
> (2) If Murder is wrong, then getting your little brother to murder people is wrong.
>
> Therefore:
>
> (3) Getting your little brother to murder people is wrong.

If the semantic function of 'Murder is wrong' as it occurs within an asserted context in (1) is different from its semantic function as it occurs within an unasserted context in (2), isn't someone arguing in this way simply guilty of equivocation? In order for the argument to be valid, the occurrence of 'Murder is wrong' in (1) has to *mean the same thing* as the occurrence of 'Murder is wrong' in (2). But if 'Murder is wrong' has a different semantic function in (1) and (2), then it certainly doesn't mean the same thing in (1) and (2). So the above argument is apparently no more valid than:

> (4) My beer has a head on it.
>
> (5) If something has a head on it, then it must have eyes and ears.
>
> Therefore:
>
> (6) My beer must have eyes and ears.

This argument is obviously invalid, because it relies on an equivocation on two senses of 'head', in (4)

and (5) respectively.

It is perhaps worth stressing why the Frege-Geach problem doesn't afflict ethical theories which see ‘Murder is wrong’ as truth-apt, and sincere utterances of ‘Murder is wrong’ as capable of expressing straightforwardly truth-asessable beliefs. According to theories like these, moral *modus ponens* arguments such as the argument above from (1) and (2) to (3) are just like non-moral cases of *modus ponens* such as

> (7) It is raining;
>
> (8) If it is raining then the streets are wet;
>
> Therefore,
>
> (9) the streets are wet.

Why is this non-moral case of *modus ponens* not similarly invalid in virtue of the fact that ‘It is raining’ is asserted in (7), but not in (8)? The answer is of course that the state of affairs asserted to obtain by ‘It is raining’ in (7) is the same as that merely hypothesised to obtain in (8). In (7) ‘It is raining’ is used to assert that a state of affairs obtains (it's raining), and in (8) it is asserted that if that state of affairs obtains, so does another (the streets being wet). Throughout, the semantic function of the sentences concerned is given in terms of the states of affairs asserted to obtain in simple assertoric contexts. And it is difficult to see how an emotivist can say anything analogous to this with respect to the argument from (1) and (2) to (3): it is difficult to see how the semantic function of ‘Murder is wrong’ in the antecedent of (2) could be given in terms of the sentiment it allegedly expresses in (1).

The Frege-Geach challenge to the emotivist is thus to answer the following question: how can you give an emotivist account of the occurrence of moral sentences in ‘unasserted contexts’—such as the antecedents of conditionals—without jeopardising the intuitively valid patterns of inference in which those sentences figure? Philosophers wishing to develop an expressivistic alternative to moral realism have expended a great deal of energy and ingenuity in devising responses to this challenge. See in particular Blackburn's development of ‘quasi-realism’, in his (1984) Chs 5 and 6, (1993) Ch.10, (1998) Ch.3 and Gibbard's ‘norm-expressivism’, in his (1990) Ch.5. For criticism see Hale (1993) and (2002). For an overview, see Miller (2003), Chs 4 and 5.

6. Against the Independence Dimension (I): Semantic Realism

Challenges to the existence dimension of realism have been outlined in previous sections. In this section some forms of non-realism that are neither error-theoretic nor expressivist will be briefly introduced. The forms of non-realism view the sentences of the relevant area as (against the expressivist) truth-apt, and (against the error-theorist) at least sometimes true. The existence dimension of realism is thus left intact.

What is challenged is the independence dimension of realism, the claim that the objects distinctive of the area exist, or that the properties distinctive of the area are instantiated, independently of anyone's beliefs, linguistic practices, conceptual schemes, and so on.

Classically, opposition to the independence dimension of realism about the everyday world of macroscopic objects took the form of *idealism*, the view that the objects of the everyday world of macroscopic objects are in some sense *mental*. As Berkeley famously claimed, tables, chairs, cats, the moons of Jupiter and so on, are nothing but ideas in the minds of spirits:

> All the choir of heaven and furniture of the earth, in a word all those bodies which compose the mighty frame of the world, have not any subsistence without a mind (Berkeley 1710: §6).

Idealism has long been out of favour in contemporary philosophy, but those who doubt the independence dimension of realism have sought more sophisticated ways of opposing it. One such philosopher, Michael Dummett, has suggested that in some cases it may be appropriate to reject the independence dimension of realism via the rejection of semantic realism about the area in question (see Dummett 1978 and 1993). This section contains a brief explanation of semantic realism, as characterised by Dummett, Dummett's views on the relationship between semantic realism and realism construed as a metaphysical thesis, and an outline of some of the arguments in the philosophy of language that Dummett has suggested might be wielded against semantic realism.

It is easiest to characterise semantic realism for a mathematical domain. It is a feature of arithmetic that there are some arithmetical sentences for which the following holds true: we know of no method that will guarantee us a proof of the sentence, and we know of no method that will guarantee us a disproof or a counterexample either. One such is Goldbach's Conjecture:

> (G) Every even number is the sum of two primes.

It is possible that we may come across a proof, or a counterexample, but the key point is that we do not know a method, or methods, the application of which is guaranteed to yield one or the other. A semantic realist, in Dummett's sense, is one who holds that our understanding of a sentence like (G) consists in knowledge of its truth-condition, where the notion of truth involved is *potentially recognition-transcendent* or *bivalent*. To say that the notion of truth involved is potentially recognition-transcendent is to say that (G) may be true (or false) even though there is no guarantee that we will be able, in principle, to recognise that that is so. To say that the notion of truth involved is bivalent is to accept the unrestricted applicability of the law of bivalence, that every meaningful sentence is determinately either true or false. Thus the semantic realist is prepared to assert that (G) is determinately either true or false, regardless of the fact that we have no guaranteed method of ascertaining which. (Note that the precise relationship between the characterisation in terms of bivalence and that in terms of potentially recognition-transcendent truth is a delicate matter that will not concern us here. See the Introduction to Wright 1993 for some excellent discussion. It is also important to note that in introducing the idea that a speaker's understanding of a sentence consists in her knowledge of its truth-condition, Dummett is packing more

into the notion of truth than the disquotational properties made use of in §1 above. See Dummett's essay 'Truth', in his 1978).

Dummett makes two main claims about semantic realism. First, there is what Devitt (1991a) has termed the *metaphor thesis*: This denies that we can even *have* a literal, austerely metaphysical characterisation of realism of the sort attempted above with Generic Realism. Dummett writes, of the attempt to give an austere metaphysical characterisation of realism about mathematics (platonic realism) and what stands opposed to it (intuitonism):

> How [are] we to decide this dispute over the ontological status of mathematical objects[?] As I have remarked, we have here two metaphors: the platonist compares the mathematician with the astronomer, the geographer or the explorer, the intuitionist compares him with the sculptor or the imaginative writer; and neither comparison seems very apt. The disagreement evidently relates to the amount of freedom that the mathematician has. Put this way, however, both seem partly right and partly wrong: the mathematician has great freedom in devising the concepts he introduces and in delineating the structure he chooses to study, but he cannot prove just whatever he decides it would be attractive to prove. How are we to make the disagreement into a definite one, and how can we then resolve it? (1978: xxv).

According to the *constitution thesis*, the literal content of realism *consists in* the content of semantic realism. Thus, the literal content of realism about the external world is constituted by the claim that our understanding of at least some sentences concerning the external world consists in our grasp of their potentially recognition-transcendent truth-conditions. The spurious 'debate' in metaphysics between realism and non-realism can thus become a genuine *debate* within the theory of meaning: should we characterise speakers' understanding in terms of grasp of potentially recognition-transcendent truth-conditions? As Dummett puts it:

> The dispute [between realism and its opponents] concerns the notion of truth appropriate for statements of the disputed class; and this means that it is a dispute concerning the kind of *meaning* which these statements have (1978: 146).

Few have been convinced by either the metaphor thesis or the constitution thesis. Consider Generic Realism in the case of the world of everyday macroscopic objects and properties:

> (GR1) Tables, rocks, mountains, seas, and so on exist, and the fact that they exist and have properties such as mass, size, shape,colour, and so on, is (apart from mundane empirical dependencies of the sort sometimes encountered in everyday life) independent of anyone's beliefs, linguistic practices, conceptual schemes, and so on.

Dummett may well call for some non-metaphorical characterisation of the independence claim which this involves, but it is relatively easy to provide one such characterisation by utilising Dummett's own notion

of recognition-transcendence:

> (GR2) Tables, rocks, mountains, seas, and so on exist, and the fact that they exist and have properties such as mass, size, shape,colour, and so on, is (apart from mundane empirical dependencies of the sort sometimes encountered in everyday life) independent of anyone's beliefs, linguistic practices, conceptual schemes, and so on. Tables, rocks, mountains, seas, and so on exist, and in general there is no guarantee that we will be able, even in principle, to recognise the fact that they exist and have properties such as mass, size, shape, colour, and so on.

On the face of it, there is nothing metaphorical in (GR2) or, at least if there is, some argument from Dummett to that effect is required. This throws some doubt on the metaphor thesis. And there is nothing distinctively semantic about (GR2), and this throws some doubt on the constitution thesis. Whereas for Dummett, the essential realist thesis is the meaning-theoretic claim that our understanding of a sentence like (G) consists in knowledge of its potentially recognition-transcendent truth-condition, for Devitt:

What has truth to do with Realism? On the face of it, nothing at all. Indeed, "Realism says nothing semantic at all beyond … making the negative point that our semantic capacities do *not* constitute the world." (1991a: 39)

Devitt's main criticism of the constitution thesis is this: the literal content of realism about the external world is not given by semantic realism, since semantic realism is consistent with an *idealist* metaphysics of the external world. He writes:

> Does [semantic realism] entail Realism? It does not. Realism … requires the objective independent existence of common-sense physical entities. Semantic Realism concerns physical *statements* and has no such requirement: *it says nothing about the nature of the reality that makes those statements true or false*, except that it is [at least in part potentially beyond the reach of our best investigative efforts]. An idealist who believed in the … existence of a purely mental realm of sense-data could subscribe to [semantic realism]. He could believe that physical statements are true or false according as they do or do not correspond to the realm of sense-data, whatever anyone's opinion on the matter: we have no 'incorrigible knowledge' of sense-data. … In sum, mere talk of truth will not yield any particular ontology. (1983: 77)

Suppose that Dummett's metaphor and constitution theses are both implausible. Would it follow that the arguments Dummett develops against semantic realism have *no* relevance to debates about the plausibility of realism about everyday macroscopic objects (say), construed as a purely metaphysical thesis as in (GR2)? Dummett's arguments can retain their relevance to metaphysical debate even if the metaphor and constitution theses are false, and, indeed, even if Dummett's view (1973: 669) that the theory of meaning is the foundation of all philosophy is rejected. For a full development of this line of argument, see Miller 2003b.

Suppose that we are considering some region of discourse *D*, the sentences of which we intuitively understand. Suppose, for *reductio*, that the sentences of *D* have potentially recognition-transcendent truth-conditions. Thus,

> (1) We understand the sentences of *D*.

> (2) The sentences of *D* have recognition-transcendent truth-conditions.

Now, from (1) together with the Fregean thesis that to understand a sentence is to know its truth-conditions (see Miller 1998, Chs 1 and 2), we have:

> (3) We know the truth-conditions of the sentences of *D*.

We now add the apparently reasonable constraint on ascriptions of knowledge:

> (4) If a piece of knowledge is ascribed to a speaker, then it must be at least in principle possible for that speaker to have *acquired* that knowledge.

So,

> (5) It must be at least in principle possible for us to have acquired knowledge of the recognition-transcendent truth-conditions of *D*.

But,

> (6) There is no plausible story to be told about how we could have acquired knowledge of recognition-transcendent truth-conditions.

So, by *reductio*, we reject (2) to get:

> (7) The sentences of *D* do not have recognition-transcendent truth-conditions, so semantic realism about the subject matter of *D* must be rejected.

The crucial premise here is obviously (6). Wright puts the point as follows:

How are we supposed to be able to *form* any understanding of what it is for a particular statement to be true if the kind of state of affairs which it would take to make it true is conceived, *ex hypothesi*, as something beyond our experience, something which we cannot confirm and which is insulated from any distinctive impact on our consciousness?(1993: 13).

However, Wright then more or less concedes that the acquisition argument can be neutralised by invoking

the *compositionality* of meaning and understanding:

> [T]he realist seems to have a very simple answer. Given that the understanding of statements in general is to be viewed as consisting in possession of a concept of their truth-conditions, acquiring a concept of an evidence-transcendent state of affairs is simply a matter of acquiring an understanding of a statement for which that state of affairs would constitute the truth-condition. And such an understanding is acquired, like the understanding of any previously unheard sentence in the language, by understanding the constituent words and the significance of their mode of combination. (1993: 16)

Dummett's challenge to semantic realism, then, turns on his second argument, the *manifestation argument*. Suppose that we are considering region of discourse *D* as before. Then:

> (1) We understand the sentences of *D*.

Suppose, for *reductio*, that

> (2) The sentences of *D* have recognition-transcendent truth-conditions.

From (1) and and the Fregean thesis that to understand a sentence is to know its truth-conditions, we have:

> (3) We know the truth-conditions of the sentences of *D*.

We then add the following premise, which stems from the Wittgensteinian insight that understanding does not consist in the possession of an inner state, but rather in the possession of some practical ability (see Wittgenstein 1958):

> (4) If speakers possess a piece of knowledge which is constitutive of linguistic understanding, then that knowledge should be *manifested* in speakers' use of the language i.e. in their exercise of the practical abilities which constitute linguistic understanding.

It now follows from (1), (2) and (3) that:

> (5) Our knowledge of the recognition-transcendent truth-conditions of the sentences of *D* should be manifested in our use of those sentences, i.e. in our exercise of the practical abilities which constitute our understanding of *D*.
>
> Since
>
> (6) Such knowledge is never manifested in the exercise of the practical abilities which constitute our understanding of *D*,

It follows that

> (7) We do not possess knowledge of the truth-conditions of *D*.

(7) and (3) together give us a contradiction, whence, by *reductio*, we reject (2) to obtain:

> (8) The sentences of *D* do not have recognition-transcendent truth-conditions, so semantic realism about the subject matter of *D* must be rejected.

The basic point is that, so far as an account of speakers' understanding goes, the ascription of knowledge of recognition-transcendent truth-conditions is simply *redundant*: there is no good reason for ascribing it. Consider one of the sentences introduced earlier as a candidate for possessing recognition-transcendent truth-conditions ‘Every even number greater than two is the sum of two primes’. The semantic realist views our understanding of sentences like this as consisting in our knowledge of a potentially recognition-transcendent truth-condition. But:

How can that account be viewed as a description of any *practical* ability of use? No doubt someone who understands such a statement can be expected to have many relevant practical abilities. He will be able to appraise evidence for or against it, should any be available, or to recognize that no information in his possession bears on it. He will be able to recognize at least some of its logical consequences, and to identify beliefs from which commitment to it would follow. And he will, presumably, show himself sensitive to conditions under which it is appropriate to ascribe propositional attitudes embedding the statement to himself and to others, and sensitive to the explanatory significance of such ascriptions. In short: in these and perhaps other important respects, he will show himself competent to use the sentence. But the headings under which his practical abilities fall so far involve no mention of evidence-transcendent truth-conditions (1993: 17).

This establishes (6), and the conclusion follows swiftly.

A detailed assessment of the plausibility of Dummett's arguments is impossible here. For a full response to the manifestation argument, see Miller 2003c. For the acquisition argument, see Miller 2003d. Wright develops a couple of additional arguments against semantic realism. For these—the argument from rule-following and the argument from normativity—see the Introduction to Wright 1993. For an excellent survey of the literature on Dummett's arguments against semantic realism, see Hale 1997.

7. Against the Independence Dimension (II): More Forms of Anti-Realism

Suppose that one wished to develop a non-realist alternative to, say, moral realism. Suppose also that one is persuaded of the unattractiveness of both error-theoretic and expressivist forms of non-realism. That is

to say, one accepts that moral sentences are truth-apt, and, at least in some cases, true. Then the only option available would be to deny the independence dimension of moral realism. But so far we have only seen one way of doing this: by admitting that the relevant sentences are truth-apt, sometimes true, and possessed of truth-conditions which are not potentially recognition-transcendent. But this seems weak: it seems implausible to suggest that a moral realist must be committed to the potential recognition-transcendence of moral truth. It therefore seems implausible to suggest that a non-expressivistic and non-error-theoretic form of opposition to realism must be committed to simply denying the potential recognition-transcendence of moral truth, since many who style themselves moral realists will deny this too. As Wright puts it:

> There are, no doubt, kinds of moral realism which do have the consequence that moral reality may transcend all possibility of detection. But it is surely not essential to any view worth regarding as realist about morals that it incorporate a commitment to that idea. (1992: 9)

So, if the debate between a realist and a non-realist about the independence dimension doesn't concern the plausibility of semantic realism as characterised by Dummett, what does it concern? (Henceforth a non-error-theoretic, non-expressivist style of non-realist is referred to as an anti-realist). Wright attempts to develop some points of contention, (or ‘realism-relevant cruces’ as he calls them) over which a realist and anti-realist could disagree. Wright's development of this idea is subtle and sophisticated and only a crude exposition of a couple of his realism-relevant Cruces can be given here.

The first of Wright's realism-relevant Cruces to be considered here concerns the capacity of states of affairs to figure ineliminably in the explanation of features of our experience. The idea that the explanatory efficacy of the states of affairs in some area has something to do with the plausibility of a realist view of that area is familiar from the debates in meta-ethics between philosophers such as Nicholas Sturgeon (1988), who believe that irreducibly moral states of affairs do figure ineliminably in the best explanation of certain aspects of experience, and opponents such as Gilbert Harman (1977), who believe that moral states of affairs have no such explanatory role. This suggests a ‘best explanation test’ which, crudely put, states that realism about a subject matter can be secured if its distinctive states of affairs figure ineliminably in the best explanation of aspects of experience. One could then be a non-expressivist, non-error-theoretic, anti-realist about a particular subject matter by denying that the distinctive states of that subject do have a genuine role in best explanations of aspects of our experience. And the debate between this style of anti-realist and his realist opponent could proceed independently of any questions concerning the capacity of sentences in the relevant area to have potentially recognition-transcendent truth values.

For reasons that needn't detain us here, Wright suggests that this ‘best explanation test’ should be superseded by questions concerning what he calls *width of cosmological role* (1992, Ch.5). The states of affairs in a given area have narrow cosmological role if they cannot contribute to the explanation of things *other* than our beliefs about that subject-matter (or other than *via* explaining our beliefs about that subject matter). This will be an anti-realist position. One style of realist about that subject matter will say that its states of affairs have wide cosmological role: they do contribute to the explanation of things other than

our beliefs about the subject matter in question (or other than via explaining our beliefs about that subject matter). It is relatively easy to see why width of cosmological role could be a bone of contention between realist and anti-realist views of a given subject matter: it is precisely the width of cosmological role of a class of states of affairs—their capacity to explain things other than, or other than via, our beliefs, in which their independence from our beliefs, linguistic practices, and so on, consists. Again, the debate between someone attributing a narrow cosmological role to a class of states of affairs and someone attributing a wide cosmological role could proceed independently of any questions concerning the capacity of sentences in the relevant area to have potentially recognition-transcendent truth values.

Wright thinks that it is arguable that moral discourse does not satisfy width-of-cosmological role. Whereas a physical fact—such as a pond's being frozen over—can contribute to the explanation of *cognitive effects* (someone's believing that the pond is frozen over), *effects on sentient, but non-conceptual creatures* (the tendency of goldfish to cluster towards the bottom of the pond), *effects on us as physically interactive agents* (someone's slipping on the ice), and *effects on inanimate matter* (the tendency of a thermometer to read zero when placed on the surface), moral facts seem only to contribute to the explanation of the first sort of effect:

> [I]t is hard to think of anything which is true of sentient but non-conceptual creatures, or of mobile organisms, or of inanimate matter, which is true because a … moral fact obtains and in whose explanation it is unnecessary to advert to anyone's appreciation of that moral fact (1996: 16).

Thus, we have a version of anti-realism about morals that is non-expressivist and non-error-theoretic and can be framed independently of considerations about the potential of moral sentences to have recognition-transcendent truth-values: moral sentences are truth-apt, sometimes true, and moral states of affairs have narrow cosmological role.

The second of Wright's realism-relevant Cruces to be considered involves the notion of judgement-dependence. Suppose that we are considering a particular region of discourse *D* in which ‘*P*’ is a representative central predicate. Consider the opinions formed by the practitioners of that discourse, formed under conditions which are, for that discourse, cognitively ideal: call such opinions *best opinions*, and the cognitively ideal conditions the *C-conditions.* Suppose we find that the best opinions formed by the practitioners covary with the facts about the instantiation of ‘*P*’. Then, Wright suggests, there are two ways in which we might seek to explain this covariance. On the one hand, we might take best opinions to be playing at most a *tracking* role: best opinions are just extremely good at tracking independently constituted truth-conferring states of affairs. In such a case, best opinion plays merely an *extension-reflecting* role, serving merely to reflect the independently determined extensions of the central predicates of *D* (or equivalently, the independently determined extension of the truth-predicate applicable in *D*). On the other hand, we might try to explain the covariance of best opinion and fact by assigning to best opinion an altogether different sort of role. Rather than viewing best opinion as merely tracking the facts about the extensions of the central predicates of *D*, we can view them as themselves *determining* those very extensions. Best opinion, on this sort of view, does not serve merely to track independently constituted states of affairs which determine the extensions of the central predicates of *D*: rather, best

opinion serves to determine those extensions and so to play an *extension-determining* role. When the covariance of best opinion and the facts about the instantiation of the central predicates of a region of discourse admits of this latter sort of explanation, the predicates of that region are said to be *judgement-dependent*; when it admits only of the former sort of explanation, the predicates are said to be *judgement-independent*.

How do we determine whether the central predicates of a region of discourse are judgement-dependent? Wright's discussion proceeds by reference to what he terms *provisional equations*. These have the following form:

> (PE) $\forall x[C \rightarrow (\text{A suitable subject } s \text{ judges that } Px \leftrightarrow Px)]$

where '*C*' denotes the conditions (the *C*-conditions) which are cognitively ideal for forming the judgement that *x* is *P*. The predicate 'P' is then said to be judgement-dependent if and only if the provisional equation meets the following four conditions:

> *The A Prioricity Condition:* The provisional equation must be *a priori* true: there must be *a priori* covariance of best opinions and truth. (Justification: 'the truth, if it is true, that the extensions of [a class of concept] are constrained by idealised human response—best opinion—ought to be available purely by analytic reflection on those concepts, and hence available as knowledge *a priori*'(Wright 1992: 117)). This is because the thesis of judgement-dependence is the claim that, for the region of discourse concerned, best opinion is the *conceptual ground* of truth).
>
> *The Substantiality Condition* The *C*-conditions must be specifiable *non-trivially*: they cannot simply be described as conditions under which the subject has 'whatever it takes' to form the right opinion concerning the subject matter at hand.(Justification: without this condition, *any* predicate will turn out to be judgement-dependent, since for any predicate *Q* it is going to be an *a priori* truth that our judgements about whether *x* is *Q*, formed under conditions which have 'whatever it takes' to ensure their correctness, will covary with the facts about the instantiation of *Q*-ness. We thus require this condition on pain of losing the distinction between judgement-dependent and judgement-independent predicates altogether).
>
> *The Independence Condition*: The question as to whether the *C*-conditions obtain in a given instance must be logically independent of the class of truths for which we are attempting to give an extension-determining account: for specifying what makes an opinion best must not presuppose some logically prior determination of the extensions putatively determined by best opinions. (Justification: if we have to assume, say, certain facts about the extension of *P* in the specification of the conditions under which opinions about *P* count as best, then we cannot view best opinions as somehow constituting those facts, since specifying whether a given opinion is best would then presuppose some logically *prior* determination of the very facts allegedly constituted by best opinions).

> *The Extremal Condition*: There must be no better way of accounting for the *a priori* covariance: no better account, other than according best opinion an extension-determining role, of which the satisfaction of the foregoing three conditions is a consequence. (Justification: without this condition, the satisfaction of the foregoing conditions would be consistent with the thought that certain states of affairs are judgement-independent even though infallibly detectable,'states of affairs in whose determination facts about the deliverances of best opinions are in no way implicated although there is, *a priori,* no possibility of their misrepresentation' (Wright 1992: 123)).

When all of the above conditions can be shown to be satisfied, we can accord best opinion an extension-determining role, and describe the subject matter as judgement-dependent. If these conditions cannot collectively be satisfied, best opinion can be assigned, at best, a merely extension-reflecting role.

Two points are worth making. First, it is again relatively easy to see why the question of judgement-dependence can mark a bone of contention between realism and anti-realism. If a subject matter is judgement-dependent we have a concrete sense in which the independence dimension of realism fails for that subject matter: there is a sense in which that subject matter is not entirely independent of our beliefs, linguistic practices, and so on. Second, the debate about the judgement-dependence of a subject matter is, on the face of it at least, independent of the debate about the possibility of recognition-transcendent truth in that area.

Wright argues (1989) that facts about colours and intentions are judgement-dependent, so that we can formulate a version of anti-realism about colours (intentions) that views ascriptions of colours (intentions) as truth-apt and sometimes true, and truth in those areas as judgement-dependent. In contrast to this, Wright argues (1988) that morals cannot plausibly be viewed as judgement-dependent, so that a thesis of judgement-dependence is not a suitable vehicle for the expression of a non-expressivistic, non-error-theoretic, version of anti-realism about morality.

For discussion of further allegedly realism-relevant Cruces, such as *cognitive command*, see Wright 1992. For critical discussion of Wright on cognitive command, see Shapiro and Taschek 1996.

8. Undermining the Debate: Quietism

Some of the ways in which non-realist theses about a particular subject matter can be formulated and motivated have been described above. Quietism is the view that significant metaphysical debate between realism and non-realism is impossible. Gideon Rosen nicely articulates the basic quietist thought:

> We *sense* that there is a heady metaphysical thesis at stake in these debates over realism—a question on a par with the issues Kant first raised about the status of nature. But after a point, when every attempt to say just what the issue is has come up empty, we have no real

> choice but to conclude that despite all the wonderful, suggestive imagery, there is ultimately nothing in the neighborhood to discuss (1994: 279).

Quietism about the ‘debate’ between realists and their opponents can take a number of forms. One form might claim that the idea of a significant debate is generated by unsupported or unsupportable philosophical theses about the relationship of the experiencing and minded subject to their world, and that once these theses are exorcised the ‘debate’ will gradually wither away. This form of quietism is often associated with the work of the later Wittgenstein, and receives perhaps its most forceful development in the work of John McDowell (see in particular McDowell 1994). Other forms of quietism may proceed in a more piecemeal fashion, taking constraints such as Wright's realism-relevant Cruces and arguing on a case-by-case basis that their satisfaction or non-satisfaction is of no metaphysical consequence. This is in fact the strategy pursued in Rosen 1994. He makes the following remarks regarding the two realism-relevant Cruces considered in the previous section.

Suppose that:

> (F) It is *a priori* that: *x* is funny if and only if we would judge *x* funny under conditions of full information about *x*s relevant extra-comedic features

and suppose that (F) satisfies (in addition to a prioricity) the various other constraints that Wright imposes on his provisional equations ((F) is actually not of the form of a provisional equation, but this is not relevant to our purposes here). Rosen questions whether this would be enough to establish that the facts about the funny are in some metaphysically interesting sense ‘less real’ or ‘less objective’ than facts (such as, arguably, facts about shape) for which a suitable equation cannot be constructed.

In a nutshell, Rosen's argument proceeds by inviting us to assume the perspective of an anthropologist who is studying us and who ‘has gotten to the point where he can reliably determine which jokes we will judge funny under conditions of full relevant information’(1994: 302). Rosen writes:

> [T]he important point is that from [the anthropologist's] point of view, the facts about the distribution of [the property denoted by our use of ‘funny’] are ‘mind-dependent’ only in the sense that they supervene directly on facts about our minds. But again, this has no tendency to undermine their objectivity … [since] we have been given no reason to think that the facts about what a certain group of people would think after a certain sort of investigation are anything but robustly objective (1994: composed from 300 and 302).

How plausible is this attempt to deflate the significance of the discovery that the subject matter of a particular area is, in Wright's sense, judgement-dependent? Argument—as opposed to the trading of intuitions—at this level is difficult, but Rosen's claim here is very implausible. Suppose we found out that facts about the distribution of gases on the moons of Jupiter supervened directly on facts about our minds. Would the threat we then felt to the objectivity of facts about the distribution of gases on the moons of Jupiter be at all assuaged by the reflection that facts about the mental might themselves be susceptible to

realistic treatment? It seems doubtful. Fodor's *Psychosemantics* would not offer much solace to realists in the world described in Berkeley's *Principles*. Rosen's claim derives some of its plausibility from the fact that he uses examples, such as the funny and the constitutional, where our pre-theoretical attachment to a realist view is very weak: it may be that the judgement-dependence of the funny doesn't undermine our sense of the objectivity of humour simply because the level of objectivity we pretheoretically expect of comedy is quite low. So although there is no knock-down argument to Rosen's claim, it is much more counterintuitive than he would be willing to admit.

Rosen also questions whether there is any intuitive connection between considerations of width of cosmological role and issues of realism and non-realism. Rosen doubts in particular that there is any tight connection between facts of a certain class having only narrow cosmological role and mind-dependence in any sense relevant to the plausibility of realism. He writes:

> It is possible to imagine a subtle physical property *Q* which, though intuitively thoroughly objective, is nonetheless nomically connected in the first instance only with brain state *B*—where this happens to be the belief that things are *Q*. This peculiar discovery would not undermine our confidence that *Q* was an objective feature of things, as it should if [a feature of objects is less than fully objective if it has narrow cosmological role] (1994: 312).

It seems to me that, at least in the first instance, Wright has a relatively quick response to this point at his disposal. Waiving the point that in any case the width of cosmological role constraint applies to *classes* of properties and facts, he can point out that in the example constructed by Rosen the narrowness of Q's cosmological role is an *a posteriori* matter. Whereas what we want is that the narrowness of cosmological role is an *a priori* matter: one does not need to conduct an empirical investigation to convince oneself that facts about the funny fail to have wide cosmological role.

Wright thus has the beginnings of answers to Rosen's quietist attack on his use of the notions of judgement-dependence and width of cosmological role. It is not possible to deal fully with these arguments here, let alone with the other quietist arguments in Rosen's paper, or the arguments of other quietists such as McDowell, beyond giving a flavour of how quietism might be motivated and how those active in the debates between realists and their opponents might start to respond.

9. Concluding Remarks and Apologies

This discussion of realism and of the forms that non-realist opposition may take is far from exhaustive, and aims only to give the reader a sense of what to expect if they delve deeper into the issues. In particular, nothing has been mentioned about the work of Hilary Putnam, his characterisation of 'metaphysical realism', and his so-called 'model-theoretic' argument against it. Putnam's writings are extensive, but one could begin with Putnam 1981 and 1983. For critical discussion, see Hale and Wright 1997. Nor have issues about the metaphysics of modality and possible worlds been discussed. The *locus classicus* in this area is Lewis 1986. For commentary, see Divers 2002. And the very important topic of

scientific realism has not been touched upon. For an introductory treatment and suggestions for further reading, see Bird 1998 Ch. 4. Finally, it has not been possible to include any discussion of realism about intentionality and meaning. The *locus classicus* in recent philosophy is Kripke 1982. For a robustly realistic view of the intentional, see Fodor 1987. For a collection of some of the central secondary literature, see Miller and Wright 2002.

Modal Fictionalism

Questions about necessity (or what has to be, or what cannot be otherwise) and possibility (or what can be, or what could be otherwise) are questions about *modality*. *Fictionalism* is an approach to theoretical matters in a given area which treats the claims in that area as being in some sense analogous to fictional claims: claims we do not literally accept at face value, but which we nevertheless think serve some useful function. However, despite its name, "Modal Fictionalism" in its usual manifestations is not primarily fictionalism about claims of necessity and possibility, but rather a fictionalist approach to claims about possible worlds. (For instance, modal fictionalism is not normally fictionalist about the claim that "it is possible that there be a species of tail-less kangaroo", but rather about the claim that "there is a possible world in which there is a species of tail-less kangaroo".) The practice of taking possible worlds to be merely convenient fictions, or of treating talk about possible worlds as being useful without being literally correct, is quite common in philosophical circles. It is only recently, however, that philosophers have seriously examined the implications of taking possible worlds to be merely fictional objects, like Sherlock Holmes or a frictionless surface.

Theories employing possible worlds terminology have been found to be very useful in philosophy, e.g. when engaging in thought experiments; distinguishing various claims in metaphysics, or in the philosophy of language, mind, knowledge or ethics; and in areas other than philosophy, like linguistics, modal logic, and probability theory. Many have found the status of these worlds and their contents to be puzzling, to say the least. What are they? Where, if anywhere, are they supposed to be? How are we supposed to discover facts about them? Isn’t it extravagant to believe that just because a situation is possible, it must in some sense exist? Modal fictionalists take theories committed to the existence of possible worlds, merely hypothetical situations, non-actual but possible objects etc. to be strictly and literally false, and so they avoid the problems of believing in possible worlds. Nevertheless, they claim, they can enjoy the benefits of using these seemingly problematic theories.

Modal fictionalism should be of interest to those concerned with the metaphysics of modality, since theories committed to the literal existence of possible worlds (and, even more worryingly, the literal existence of merely possible objects ‘contained’ in these worlds) come at a cost, both to economy and to many people’s intuitions. But it is, or should be, of wider interest as well, since it is one of the most discussed applications of a fictionalist treatment of abstract objects, along with mathematical fictionalism. Lessons learned in the case of modal fictionalism can hopefully be applied to other areas in which we may wish to evade literal theoretical commitments.

I shall begin by discussing the motivation for modal fictionalism, and distinguishing some of its varieties.

Next, I shall seek to put fictionalism in a slightly broader theoretical context, by discussing its connections with instrumentalism and eliminativism, and by discussing what connection there might be between "fictionalism" and treatments of paradigmatic fictions. I shall then discuss the debate about the "Brock/Rosen objection" and a problem raised by Bob Hale, both of which turn on technical problems concerning modal claims about the status of the modal fiction. Finally, in section 4, other concerns about modal fictionalism will be discussed.

---

1. Types of Modal Fictionalism

Modal fictionalists often focus on the claim that possible worlds are merely fictional entities, and apparent commitment to possible worlds is to be explained in the same sort of way that apparent commitment to ideal gases or frictionless surfaces is to be explained. Rosen 1990 and others have formulated modal fictionalism as a theory that takes talk of possible worlds to be on a par with talk about paradigmatically fictional objects, e.g. Sherlock Holmes ("There is a (non-actual) possible world at which there are blue swans" is to be understood on the model of "There is a brilliant detective at 221b Baker Street", in Rosen's example). This goes with an at least partial account of how we are to treat paradigmatically fictional claims: that they are, literally and strictly speaking, false. The literal truth, according to modal fictionalists, is that there are no merely possible worlds (or merely possible situations, or outcomes), and there are no merely possible objects. Strictly and literally speaking, there is no sculpture that I spent this morning making, though there could have been. When the flipped coin comes down heads, there is strictly speaking no outcome of that very throw in which it comes down tails.

What is literally true, however, is that *according to the modal fiction*, or *according to the fiction of possible worlds* there is a (merely possible) sculpture I could have spent this morning making, and there is an (unactualised) outcome of the toss in which the coin came down tails. What is said in talk about merely possible worlds and merely possible objects is generally literally false, but the slightly more longwinded talk about what is true according to the fiction of possible worlds is literally true. One might think (as Hinckfuss 1993 does) that talk about possible worlds is (or should be) governed by implicit presuppositions known to be false so that what is *said* in the language of possible worlds does not commit one to the existence of possible worlds, but only to some more economical proposition: something of the kind "if there were possible worlds of such-and-such a sort, then ...", or "given the

presupposition that there are possible worlds, ...". Or you might have some other account of the functioning of talk about possible worlds: Nolt 1986 suggests we should take typical "possibilistic discourse" to be a game of make-believe (Nolt 1986, p. 440), and while Nolt does not tell us specifically what theory of make-believe he has in mind, there are many theories of make-believe (most famously Walton 1990) that might be employed by a modal fictionalist to explain the behaviour of our typical utterances about possible worlds.

The main benefit which a fictional approach to possible worlds offers is, of course, the advantage of using the language of possible worlds, without the stiff ontological cost of literal commitment to such worlds. It is an especially tempting account of merely possible objects (like blue swans, or dragons, or the Holy New Zealand Empire): even those who accept some abstractionist account of possible worlds (see van Inwagen 1986) might well be reluctant to accept the literal existence of their contents. After all, it is often thought that the distinguishing mark of *merely* possible objects is that they do not actually exist.

Central to fictionalist treatments of possible worlds are biconditionals connecting truths about necessity and possibility, on the one hand, and the contents of the modal fiction, on the other. Central biconditionals will be all the instances of the following schemas (where P expresses a proposition):

> Possibly P iff according to the fiction of possible worlds, P is true at some possible world.

> Necessarily P iff according to the fiction of possible worlds, P is true at all possible worlds.

Either schema will be adequate to yield the other, given the standard inter-definition of possibility and necessity, provided enough logical machinery is available for reasoning within the scope of the "according to the fiction" operator. As a matter of fact, the above is a simplification, since, according to Rosen (1990, p 335), what is true according to the fiction of possible worlds may be only a proposition connected with P: the paraphrase of P into the language of possible worlds. In general, for Rosen, this will be the analysis of P in Lewis's theory of possible worlds. Rosen states the form of the fictionalist biconditionals at its most general as:

> P iff according to PW, P*.

where "PW" is the fiction of possible worlds, P is any proposition, and P* is its possible-worlds "paraphrase" (Rosen 1990, p. 335). In simple cases the above biconditionals will do as they are: for example,

> Possibly, pigs fly iff according to the fiction of possible worlds (or according to PW), at some possible world, pigs fly.

In less straightforward cases, however, the proposition expressed by P* may have to differ from that expressed by P.[1] Fictionalists may also employ other biconditionals when constructing their fiction -

one example is a biconditional to ensure that every proposition that is (really) true is according to the fiction true in the actual world.[2] A modal fiction may require more contents than those yielded by such biconditionals: what other contents the fiction of possible worlds might contain is an important question, and one unsurprisingly which different modal fictionalists will answer differently.

1.1 The Contents of The Fiction of Possible Worlds

Many fictionalists are far from explicit about exactly what the content of the fiction of possible worlds is to be. (Often they are also silent on the pressing issue of how one would justify one fiction rather than another: but more on this in section 4). Two explicit proposals were made in 1989 and 1990 about which fiction to use. Gideon Rosen's 1990 proposed using a slightly modified version of David Lewis's 1986 theory of possible worlds as the modal fiction. The theory had been proposed by Lewis as the literal truth, but by treating it as a mere fiction Rosen provided a ready-made story about possible worlds, their extent and nature. The other proposal was that of D.M. Armstrong's 1989. Armstrong proposed a "two-step" fiction, according to which there was a "great fiction", which asserted the existence of a lot of "little fictions", each of which completely described a possible world. Armstrong resisted identifying these complete descriptions of ways things could be with the possible worlds, as an abstractionist might, since Armstrong believed that worlds are supposed to be objects like our cosmos, rather than descriptions, properties, or other such abstract objects. Armstrong employed the two stage fiction, on the other hand, because he held that it is true at each world that it is the only world, and if the fiction were of a Lewisian pluriverse each world would (according to the fiction) be such that it was one of many worlds. In this respect, though Armstrong spells out the concern in quite a different manner, it can be seen as an anticipation of the Brock/Rosen objection (see section 3, below). In both the theories of Armstrong and Rosen the "worlds" in the story are thought to be 'concrete' cosmoi, like our own.[3]

For any set of principles governing the fiction of possible worlds, the question obviously arises as to why that set should be chosen. Alternatively, there are many stories we could tell about other worlds (whether they are cosmoi or fictional abstract objects), and the question arises as to why one rather than any other be chosen to be *the* modal fiction. (One could of course be more pluralist than this, and allow that different fictions are suitable for different purposes. The relativised question may still be asked, however: why *this* fiction, rather than any other, for *this* particular purpose?). This task of selecting and justifying one or more particular stories about worlds will be one of the challenges discussed in section 4. However, the next distinction to be discussed makes a big difference to what sort of answer to this question will be acceptable.

1.2 Strong vs. Timid

This next distinction concerns the role the modal fiction is to play in the theory. Is the fiction of possible worlds intended to provide an explanation of the applicability modal vocabulary, or not? The view that the truth of modal claims depends on, or is to be explained by, the contents of the fiction of possible worlds is often called "strong modal fictionalism", following Rosen's description of such a view (Rosen 1990, p. 354, Nolan 1997a). The view that modal truth does not depend on the contents of the modal

fiction (and usually, that what the contents of the modal fiction are depends on the modal truth), on the other hand, is known as "timid modal fictionalism", again following Rosen (Rosen 1990, p. 354).

Both the view put forward by Armstrong 1989 and the primary view discussed (but not endorsed) by Rosen 1990 seem to have been fictionalisms of the ‘strong’ kind (see Nolan 1997a, p. 263). ‘Timid’ fictionalism about possible worlds is also mentioned by Rosen 1990, and has been endorsed in passing by Field (1989, p. 41, 86). A modal fictionalist theory which sees the fiction of possible worlds as providing the resources for an analysis of modal statements would of course do important theoretical work: since the analysis of claims involving modal operators is among the most controversial and difficult issues in metaphysics. The downside is that strong modal fictionalism seems to face serious objections: see section 4.

Apart from any objections that might be leveled at strong modal fictionalism, the advocate of this variety of modal fictionalism faces the challenge of stating the contents of the modal fiction without relying on modal notions in a way that would make the explanation of those modal notions circular. Since the fiction explains the truth of modal claims, explaining the content of the modal fiction by reference to modal claims would be circular (e.g. by stipulating that all of the propositions which are necessary hold in all worlds, or that objects have in all worlds in which they exist the properties which they in fact have essentially). Stating, in non-modal terms, general principles about possible worlds that would enable one to determine, when presented with a proposition, whether it holds at all worlds, at some but not others, or none, is a difficult and controversial matter. Plausibly, a strong modal fictionalist will owe us such a non-modal specification of the contents of the modal fiction, if our understanding of the contents of the modal fiction is to allow us a useful method of assessing the truth of modal claims. Furthermore the strong modal fictionalist seems committed to *there being* a fact of the matter about the content of the modal fiction which is not itself to be explained or analysed in terms of further modal facts of the matter.

One particularly pressing instance of this difficulty (noted e.g. by Rosen 1990, p. 344) is the problem of how to understand the "according to the fiction of possible worlds..." operator. Natural initial glosses, as Rosen points out, include:

> If PW were true, then P would be true; If we suppose PW, P follows; It would be impossible for PW to be true without P being true as well. (Rosen 1990, p. 344)

The problem is that these seem modal.
Rosen offers several possible responses the fictionalist could make to this problem. He could admit that his theory does indeed contain a modal primitive, but claim nevertheless that it is some sort of advance in analysis, reducing all modal primitives to one. (Though as Rosen says, "According to the fiction of possible worlds" seems like a very odd primitive.) Or he could instead attempt to spell out the prefix in a non-modal way. This has not to date been attempted by many avowed modal fictionalists, but is one of the many tasks facing a modal fictionalist who sees the invocation of the fiction as the method for analysing or explaining modality.

If the modal fictionalist were only timid, on the other hand, then the fictionalist biconditional could be used to generate a great deal of the content of the modal fiction: whether or not the fiction claims that a given proposition is true in all possible worlds (or all accessible worlds) depends on whether that proposition is indeed necessarily true; whether or not a proposition is true at some world (or some accessible world) depends on whether it is possibly true; and so on. Furthermore, an analysis of truth in fiction in terms of some modal notion (whether a counterfactual conditional, strict implication, or whatever) would not make the account circular, since analysing modal discourse would be no part of the purpose of the fictional machinery. One recent worked-out modal fictionalist approach which explicitly analyses the relevant "according to the modal fiction" operator in terms of modal operators is Divers 1999b. Among other benefits, Divers argues that this sort of definition enables one to prove a "modal safety result": that when we have two modal claims A and B, and we have the possible-worlds-analogues of the two modal claims (call them A* and B* respectively), "Necessarily, if B* is a consequence of A* then B is a consequence of A" (Divers 1999b, p. 330). Such a safety result would be welcome, for it would provide the guarantee we needed that "detouring" in our reasoning through claims like A* and B* would not lead us astray when trying to determine whether B followed from A.

A drawback of timid modal fictionalism is that it leaves the important issue of a theory of modality to one side. Without some other positive story, even if it were primitivism about modality, it might seem that it would be difficult to motivate timid fictionalism over agnosticism about the status of possible worlds. Many of the leading candidates for analysis of modal claims are those that explain the truth of modal claims in terms of the literal existence and nature of possible worlds, so without a positive alternative story, it might seem premature to reject this style of explanation of modality. However, the project of endorsing fictionalism about possible worlds and possible objects without endorsing the further claim that this fiction provides the material to explain or analyse our modal notions, while in some ways less philosophically interesting than its strong cousin, is proportionally less open to serious objections.

1.3 Normative vs. Descriptive

Modal fictionalism can be interpreted as a descriptive theory of what our talk in fact amounts to, or as a normative proposal for how we should use talk of possible worlds. (In the terminology of Burgess and Rosen 1997, this is the distinction between a "hermeneutic" construal of modal fictionalism and a "revolutionary" construal of modal fictionalism). If the theory is that in fact we take possible worlds to be no more than convenient fictions, and, in the case of strong modal fictionalism, that facts about the content and nature of the fiction of possible worlds explain and/or provide the basis of the analysis of our modal locutions, then the theory is descriptive. This sociological claim that most philosophers who talk about possible worlds take this talk to be analogous to talk of e.g. ideal gases is a dubious one: my own impression is that modal fictionalism is a minority view amongst those philosophers who work extensively on the philosophy of possible worlds and its applications, though perhaps fictionalism might be the majority view when all who have opinions on possible worlds are taken into account.

In any case, fictionalism about possible worlds might be important even if the descriptive version is

incorrect. A normative claim to the effect that talk of possible worlds *ought* to be interpreted as merely fictional discourse, or the corresponding strong fictionalist claim that modal statements *ought* to be reinterpreted so as to be explained or analysed as statements about the content of the fiction of possible worlds, might be found attractive even if it were conceded that most people who employed the discourse were not talking fictively, or that the actual commitments of the folk and most philosophers who employ everyday modal idiom are to be cashed out in some other way (e.g. as implicit commitment to some false theory, perhaps one which took modal statements to have truth conditions in terms of an objective modal reality).

The two questions, of whether the fictionalist theory is supposed to describe our current practice, and whether it is supposed to describe a practice we should adopt instead of realism, are independent. Two people could agree that normal usage of possible-worlds talk is not intended literally, but disagree about whether we should accept the literal existence of possible worlds (that is, they could be descriptive fictionalists while disagreeing about the normative question), and likewise two people could be normative fictionalists, and claim that we should take ordinary possible worlds talk as being only fictionally true or appropriate, while disagreeing about whether in fact current usage reflects this fictionalism or instead reveals non-fictionalist commitments among the users of the vocabulary. (This independence may be overlooked if we employ Burgess and Rosen’s vocabulary, which suggests that fictionalists face a binary choice of a "hermeneutic" fictionalist approach or a "revisionary" approach.)

Unfortunately, modal fictionalists have often not been explicit about whether their theory is to be an analysis of the possible-worlds talk and perhaps modal discourse which is actually employed, or a normative suggestion about how we might move to a superior theory. It is to be hoped that those seeking to provide a fully worked out modal fictionalist position would make more explicit the status of their proposal.

1.4 Fictionalism about Modality and Modal Fictionalism

So far, it has been taken for granted that the modal fictionalist treats ordinary modal claims as sometimes literally true, and it is only claims about possible worlds and their contents which the modal fictionalist will wish to claim are literally false, but true according to a story. A more radical modal fictionalism is possible: one in which modal claims themselves (such as the claim that there could have been blue swans, or that necessarily, everything is self-identical) are not literally true, but only true according to a fiction. (In Nolan 1997a I called a version of modal fictionalism which took both claims about possible worlds and modal claims to be true only according to fictions *broad* modal fictionalism.)

Such extended fictionalism about modality could, I think, come in two main varieties. One would maintain that modal operators (and associated pieces of language like essential predication, counterfactual conditionals, and perhaps other things like assignments of probabilities) lacked literal application: that all statements prefixed with a modal operator were either uniformly literally truthvalueless or uniformly literally false. This faces several immediate formal difficulties, given the usual characterisation of the modal operators.[4]

A less blanket rejection of modality might only insist on the falsehood of some modal claims: think of the analogy of a moral nihilist who rejects only "positive" moral claims, such as that taking property without permission is wrong, or that it is good to help the ill, but accepts that it is not wrong to take property without permission (since nothing is wrong) and that it is not good to help the ill (since nothing is good). This fictionalist about modality might reject the literal truth of all claims about necessity, for example (and, in virtue of the interdefinition, accept the literal truth of all possibility claims). Or she might assert as little as is needed to preserve the basic modal inferences from actuality: for example, every true P is possibly true, and actually true, but this is the limit of literal modal truth. This would be more analogous to the fictionalist about possible worlds who nevertheless thinks that there is one possible world -- the actual, and one collection of possible objects -- the actual objects.

Fictionalism of this sort extending to modal discourse as well should be a position worthy of investigation by those attracted to fictionalist strategies and mistrustful of modality. Since it seems to lack contemporary advocates, however, it shall not be dwelled upon here.[5]

1.5 Further Extensions

Modal fictionalism has traditionally been conceived as fictionalism about possible worlds, and implicitly also about their contents. One natural way to extend modal fictionalism so understood is to admit impossible worlds as well. Use of a fiction of impossible worlds is unlikely to seem too extravagant for many modal fictionalists, but it might also provide a mechanism for non-fictionalists about possible worlds to talk of impossible worlds without the extra theoretical costs they fear. So there is a partially fictionalist option of being a realist of some stripe about possible worlds but a fictionalist about impossible worlds (and perhaps other situations, e.g. incomplete or underdetermined ones). This partial fictionalism will face some of the same sorts of questions, and employ the same sorts of strategies, as modal fictionalism about *possible* worlds.

Another mixed strategy is rarely explicitly endorsed, though it may be implicit in many theorists' talk. By far the majority of realists about possible worlds take them to be abstract objects of some sort: sets of sentences or propositions, uninstantiated world-properties, or unactualised maximal facts, or perhaps even as sui generis simples. However, their approach to merely possible objects is often less explicitly spelled out. As well as possible worlds, merely possible objects such as blue swans, my counterparts, Newtonian masses, XYZ, and many others are discussed and quantified over. Some abstractionists will wish to identify such merely possible objects with actual abstract objects - perhaps uninstantiated properties that are less than world-properties, descriptions of parts of worlds, set-theoretic representatives, or whatever. But many more will not. This is for at least three reasons. The first is the intuition, never entirely quelled, that a merely possible blue swan should be *blue* and a *swan*. Abstract objects are rarely, if ever, either. The second is that it is often thought that the whole point about merely possible objects is that they do not exist, but might have. Admitting their literal existence by identifying them with actual existing abstract objects will go against the grain for many. Finally, many theories of possible worlds lack obvious candidates to play the roles of merely possible objects. This is most obvious for those theories that take possible worlds to be simples, but it is also not straightforward to divide a set

of propositions into "object shaped" components, or to distinguish one merely possible object from its duplicates if one identifies worlds with world-properties, and furthermore seeks to divide these up to yield merely possible less-than-world-sized objects. Fictionalism about merely possible objects is an underappreciated theory, and should perhaps recommend itself to more abstractionists about possible worlds than it in fact does.

2. Fictionalism in Context

2.1 Modal Fictionalism and Fiction

A theory that holds that possible worlds are to be treated as having the status of fictional objects immediately gives rise to questions about the status of fictions and fictional objects more generally. The issue of how to understand the "according to the fiction..." operator has already been mentioned. Other issues in the treatment of fiction are the question of whether "theoretical" fictions are to be seen in the same light as literary fictions, and the question of what ontological status fictions possess.

There is room in principle to distinguish claims about paradigmatically fictional characters (like Sherlock Holmes or hobbits) from the treatment one wishes to apply to claims which serve useful theoretical purposes but which are not to be taken literally, or at least not at face value: to distinguish "fabulous" and "fictional" entities, to use Bentham’s not entirely perspicuous terminology (Bentham 1959). One might wish to do this, for example, if one thought that paradigmatic story-telling consisted of utterances that were not truth-apt (not anyway through the same mechanism as ordinary utterances), while claims about, say, ideal gases were better construed as standard sorts of assertions that were literally false. In practice, however, recent modal fictionalism discussions have proceeded as if the theory holds that possible worlds are fictional in the fullest sense of the word.

The ontological status of fictions is an important issue to settle if we are to determine whether modal fictionalism is any advance metaphysically on rival realist theories of possible worlds. On pain of circularity, the ontology of fiction, as conceived by the fictionalist, had best not include possible worlds (as the ontology of fiction offered in Lewis 1978 does), but there are other sources of concern. Rosen points out that fictionalists must believe in fictions, stories, theories, or somesuch, and that if these are construed as abstract objects, they will not be philosophically uncontroversial (Rosen 1990, p. 338). Rosen argues that belief in abstract objects like stories and theories is less revisionary than belief in Lewisian possible worlds, at least. However, it is hardly clear that an ontology of abstract representational entities is any more or less objectionable than the ontology of abstractionist theories of possible worlds. (Lycan 1993, p. 16, Nolan 1997a, pp. 271-273). Alternatively, fictionalists could commit themselves to more concrete, "nominalistically respectable" fictions only: the relevant fictions or theories of possible worlds might be conceived of only as ink-marks on pieces of paper, or information states inside brains, or perhaps as some amalgam of these and other actual, concrete ontology. This approach is not problem-free either (see section 4): it is far from clear that it will serve as a basis for paradigm fictions, let alone be enough to explain possible worlds.

2.2 Fictionalism and Instrumentalism

Fictionalism about possible words, in the sense of "fictionalism" that has been used here and that is standard in the literature, can be distinguished from instrumentalism, in a way that is also standard for those who bother to distinguish them. The main difference, as usually conceived, is that a fictionalist holds that claims in the target discourse, at least made without presuppositions, are literally significant and truth-apt, but in fact false (though true according to a fiction, theory, or whatever). A traditional instrumentalist, on the other hand, is often characterised as taking the claims to lack truth-value. Some instrumentalists will go further, and say that such apparent claims are not capable of being genuinely asserted at all - their linguistic function is a different one. Be that as it may, the difference is not terribly great. In both cases, there is a realm of literal truths (e.g. truths of modality), and a realm of ‘claims’ that are not literally true, but which it is useful to advance (or manipulate in a similar way) "as if" they were true, in some respects at least. In both cases some set of biconditionals will be needed to move from literal truths to what is true according to the fiction (or acceptable in the instrumentalist discourse), and back, and both views will join in repudiating realist theories of possible worlds, while wishing to retain the legitimacy of talk *prima facie* about them.

Other versions of instrumentalism will be even more similar to fictionalism. So-called "epistemic instrumentalism", for example, does not deny that the claims of the relevant theory are truth-apt, but says merely that we should withhold belief from them (a *locus classicus* of this sort of instrumentalism about unobservables is van Fraassen 1980). Such a view is virtually the same as fictionalism, except for the cosmetic difference that it is more likely to be cast in terms of what is true "according to the theory..." (or "according to the models of the theory...") instead of "according to the fiction...", and the slightly more noteworthy difference that such instrumentalism is neutral on the question of whether the theory in question is true or false, whereas fictionalism is committed to its being false. In the case of possible worlds, one interpretation of the theory of Merrill 1978 is that it should be seen as a variety of van Fraassen-style "instrumentalism", employing semantic models of possible worlds without belief in the possible worlds themselves (indeed, while being convinced the worlds themselves do not exist). Merrill himself describes his position as "instrumentalism" about possible worlds.

Other positions in the literature are sometimes labelled "instrumentalism": for instance Forbes 1983 names his position "instrumentalism", even though he believes in the literal truth of many positive possible-worlds statements, since he claims these statements are to be understood not as straightforward quantifications over possible worlds and possible objects, but rather as equivalent to statements not quantifying over such objects. Whatever it is called, Forbes’s position on possible worlds is far removed from the other positions labelled instrumentalism here.

2.3 Fictionalism and Eliminativism

Fictionalists have in many respects only small differences from instrumentalists -- though of course the significance of differences can vary from inquiry to inquiry, and the philosophy of language issues that

arise in making the distinction are to some both interesting and important. The disagreement between fictionalists and eliminativists about possible worlds is more significant, on at least one understanding of what it is to be an eliminativist. In one sense, of course, fictionalism is a species of eliminativism, if eliminativism about possible worlds is just the doctrine that there are no such things. If, however, eliminativism about a domain is the doctrine that not only do the putative objects committed to not exist, but that discourse about (or apparently about) such objects is to be done away with, then clearly this doctrine will be in conflict with the fictionalism which seeks to give a fictionalising interpretation to possible worlds discourse just in order to salvage a useful theoretical and heuristic device without paying the ontological (and other theoretical) costs. An analogy might be drawn in the realm of theoretical entities: while fictionalism is the standard approach to apparent commitment to ideal gases, eliminativism is the contemporary approach to luminiferous ether.

Again, distinguishing fictionalism about possible worlds (and a fictionalist treatment of apparent commitment to possible worlds) from eliminativism about possible worlds (and an approach of rejection and cessation of apparent commitment to possible worlds) is to some extent an exercise in stipulation. For one could, with equal justice, count as fictionalist a position which held that possible worlds had the status of other fictional objects (i.e. non-existence), that talk of them was at best to be treated fictionalistically, but that furthermore such talk was in the end misleading or worthless or defective to the point that it should be abandoned. If one were to go this way instead, fictionalism and eliminativism would overlap. Including in fictionalism a commitment to the worth of possible-worlds discourse would rule out the view just outlined as a *fictionalist*, as opposed to eliminativist, position.

Whatever terms are used to describe the distinction (and it is unlikely that any short expressions will conveniently mark the difference without some stipulation), the distinction between those who think that our practice of apparently quantifying over possible worlds and making claims about their contents is a valuable one worth preserving, even if there are no (merely) possible worlds, or literal truths about them, and those who think that this practice should be dispensed with, perhaps *because* there are no (merely) possible worlds, or truths about them. This distinction marks an important divide among those who reject the existence of possible worlds and their contents: and however exactly the divide is drawn, typical fictionalists disagree with 'hard-core' eliminativists on this issue.

While a fictionalist, so distinguished, and an eliminativist, so distinguished, may agree to a great extent about the fundamental metaphysical issues, they may have very significant differences when it comes to philosophical practice. For an eliminativist will eschew explanations couched in terms of possible worlds, whether that be in the semantics of conditional statements, analyses of supervenience claims in ethics or philosophy of mind, possible-worlds accounts of content, explications of the operation of modal operators or probability assignments in terms of possible worlds, and so on. Fictionalists, on the other hand, will typically hope to salvage some or all of these explanations, even if an appeal to possible worlds is not quite the end of the explanatory story. It is this difference in the spirit of the eliminativist and fictionalist approaches (as here distinguished) that is the interesting difference between the views.

3. Technical Problems

There are a variety of technical objections to modal fictionalism, and if these objections succeeded they would derail specific proposals like that of Rosen 1990 and perhaps cause difficulties for modal fictionalism in general. The most discussed of these objections is the Brock/Rosen objection, an objection to the theory of Rosen 1990, published independently in Brock 1993 and Rosen 1993. (In the case of Rosen 1993, a variety was also leveled at the fictionalism of Armstrong 1989).

3.1 The Brock/Rosen Objection

The reader is advised to consult Brock 1993 and Rosen 1993 for an exact statement of their objections, but in essence the problem arises when we consider the modal status of certain claims about possible worlds themselves. One of the principal fictionalist biconditionals, as we have seen, is the biconditional connecting necessary truths and what the fiction asserts about all possible worlds:

> Necessarily P iff, according to the modal fiction, at all worlds, P*,

where P* is the possible-worlds paraphrase of P. According to the fiction employed by Rosen 1990 (i.e. the theory which David Lewis offers as fact), there are many co-existing concrete possible worlds - each one its own cosmos. Furthermore, this claim is true at any of these possible worlds. So, according to the modal fiction, at all worlds it is true that there are many other possible worlds. However, it follows from the biconditional that since, according to the modal fiction, at all worlds, there are many possible worlds, it follows that necessarily, there are many possible worlds. Since necessarily P implies P, it follows that there are (literally!) many possible worlds. But the whole point of modal fictionalism was to deny (or at least avoid asserting) that there were many possible worlds. So modal fictionalism, at least of the variety described, is self-refuting.

So the objection goes. (The version presented above is Brock's from Brock 1993 -- for some of the detail of Rosen's argument, see below or Rosen 1993.) Two direct responses have been offered to this problem in the literature. The first, by Peter Menzies and Philip Pettit (Menzies and Pettit 1994), conceded that the objection "is decisive against the letter of the Rosen proposal" (p. 29), and sought to provide modified fictionalist biconditionals to produce a modal fictionalist theory which would not be susceptible to the Brock/Rosen objection. Nolan and O'Leary-Hawthorne 1996 produced a version of the Brock/Rosen objection which they believed circumvented the Menzies and Pettit solution offered in section 3 of Menzies and Pettit's paper. Section 5 of Menzies and Pettit gave another translation scheme meant to avoid the Brock/Rosen objection; it is argued in the following supplementary document that this scheme too is unsatisfactory.

> [Supplementary Document: A Persisting Problem For Fictionalism About Possible Worlds]

I shall not dwell on the details of the Menzies/Pettit position, since the other response to the Brock/Rosen objection has been more influential: the response of Noonan 1994. Noonan claims that the Brock/Rosen

objection is not even successful against the letter of the original proposal in Rosen 1990 (Noonan 1994, p. 133). He argues that careful attention to the procedures actually given by Lewis (Lewis 1968) for paraphrasing modal claims into claims in the language of possible worlds will show that "according to the fiction of possible worlds, at any world, there are many worlds" will not be able to be derived, and so the move to "necessarily, there are many worlds" cannot be carried through. Thus if the fictionalist sticks closely to the possible-worlds "translations" given in Lewis 1968, s/he will be able to avoid the threatened collapse.

The way the Brock/Rosen objection is raised by Rosen begins with an apparently harmless statement of contingency: (numbering of claims are Rosen's, and while Brock and Rosen's presentations are reasonably informal, the formal translations are given by Noonan, and his numberings for those are provided)

> (2) Necessarily, it is contingent whether kangaroos exist

or to put it in formal modal logic ($Kx = x$ is a kangaroo):

> $\Box (\Diamond \exists x Kx \ \& \ \Diamond {\sim} \exists x Kx)$

From this, Rosen claims, the "standard analysis" delivers:

> (3) At all worlds, there are worlds where kangaroos exist and worlds where they don't.

Ignoring for our purposes the complications which need to be introduced if we are to add accessibility relations between worlds, the Lewis 1968 equivalent of (2) is

> (3L) $\forall w(Ww \rightarrow \exists w'(Ww' \ \& \ \exists x(Ixw' \ \& \ Kx)) \ \& \ \exists w''(Ww'' \ \& \ \neg\exists x(Ixw'' \ \& \ Kx))))$

Noonan points out that this formula does not imply

> (4L) $\forall w(Ww \rightarrow \exists w'(Ww' \ \& \ Iw'w \ \& \ \exists w''(Ww'' \ \& \ Iw''w \ \& \ \neg w'=w'')))$

which is the formula required in Lewis 1968 to be able to move back to "necessarily, there are two worlds", and which is the formula Brock and Rosen would need to derive if they were to show that Rosen's (2) (or Brock's equivalent) led the modal fictionalist to have to say that there are literally several worlds. The reason why (3L) does not imply (4L) is that it is not enough for there to be two worlds at a given world (V, let us call it) that there be existential quantification over two worlds within the scope of an existential quantifier committing us to V: the two worlds must also be "in" V, in the sense that the two place predicate "I" must hold between V and each of the worlds. This is what happens in (4L), but it does not happen in (3L), where there are two existential quantifiers over worlds in the scope of the outside universal quantifier, but where the worlds existentially quantified over are not asserted to be "in" any of the worlds *w*.

Rosen 1995 has accepted Noonan's resolution of the problem apparently posed by the Brock/Rosen objection. Rosen has thus changed his preferred proposal, so that instead of a general endorsement of the position outlined by Lewis 1986, Rosen's recommendation for modal fictionalists now relies more heavily on Lewis 1968. Instead of the simpler biconditionals discussed near the beginning of this entry and in Rosen 1990, the revised proposal is to take equivalences asserted by Lewis 1968 between modal claims and claims couched in terms of quantification over possible worlds, and treat those equivalences instead as specifying connections between modal statements and claims about what is true according to the fiction. If a modal claim is literally true, its associated world-claim is true according to the fiction, and vice versa.

So the state of play seems to be this: while the Brock/Rosen style objection remains something for a modal fictionalist to be wary of when constructing the fiction of possible worlds, it is possible to avoid the objection by being suitably careful about what fictionalist biconditionals to employ: and if Noonan is right, strict adherence to the fictionalist modification of the equivalences offered by Lewis 1968 provides one suitable way of being careful. It is not uncontroversial, of course, that Noonan's strategy is the one a modal fictionalist should employ: Divers 1999a and 1999b argue that it is not.

3.2 Hale's Dilemma

Bob Hale (in Hale 1995b) posed a dilemma for modal fictionalism (more specifically, Rosen's version of modal fictionalism, though other varieties face a similar dilemma). A modal fictionalist who maintains the version outlined in Rosen 1990 believes that the fiction of possible worlds (PW) is not literally true. A question arises about the modal status of the fiction: is it necessarily false, or contingently false? In either case, Hale argues, the modal fictionalist is in trouble.

Should modal fictionalists claim that the story of possible worlds is necessarily false, then Hale argues that they cannot gloss their "according to the fiction of possible worlds ... ." prefix as "were the fiction of possible worlds true, then ... would be true". This is because, according to Hale, conditional claims with antecedents which are necessarily false are automatically true, so if the fiction of possible worlds is taken to be necessarily false, then all conditionals of the form "were the fiction of possible worlds true then ..." are true, and not merely the ones that the modal fictionalist wishes to endorse. If the modal fiction is to be useful, not everything should be true according to it: examples of claims that had better not be true according to it include the claim that 2+2=7, or the claim that there are no possible worlds.

On the other hand, if the fiction of possible worlds (PW) is only contingently false, Hale claims this also lands the Rosen's fictionalism in trouble, since if its falsehood is only contingent, then the fiction might have been literally true (or it is possible that the fiction be true). But according to Hale the "official fictionalist paraphrase" of what this possibility would amount to "cannot adequately capture the content of the claim that possibly PW is true". (p 65) Hale claims this is so because the claim "According to PW, there is a possible world at which PW is true" is equivalent for Rosen's fictionalist to "If PW were true, there would be a world at which PW is true": and this conditional is one which would be true whether or

not PW was true.

A modal fictionalist might try to resist either horn of the dilemma. On the first horn, modal fictionalists might employ another gloss on what it is to be true according to PW, or they might endorse one of the various theories of conditionals on which conditionals with necessarily false antecedents are not automatically true. On the second horn, even fictionalists who accepted that they were committed to analysing their claim that PW could have been true as "If PW were true, there would be a world at which PW is true" could dispute Hale's claim that this is inadequate (see for example Divers 1999b p 325-326).

A third option, explored by Rosen 1995, is not to take PW to be false, but rather altogether lacking a truth-value -- e.g., in virtue of employing terms with no literal application, such as "... is a world-mate of...". Hale's dilemma is directed primarily against fictionalists who take the literal content of their fiction to be false, and those fictionalists prepared to ascribe some other status to their fictional claims avoid the dilemma as initially stated (though this route may encounter difficulties of its own, especially if it retains some sort of conditional analysis of the "according to PW" prefix).

Rosen 1995 and Divers 1999b are among the responses to Hale, and Hale has in turn responded to Rosen 1995 in Hale 1995a, where Hale argues that several of the responses suggested by Rosen in turn face serious problems.

4. Other Concerns

In addition to the technical challenges facing modal fictionalism outlined in the previous section, modal fictionalism has been challenged on a number of less technical grounds. Not all of these challenges are equally cogent against every variety of modal fictionalism, and some explicitly have as their targets only some versions of the doctrine.

4.1 Artificiality

Fictions are human products: they have authors, and those authors have a good deal of control over what is true according to them (though some fashionable postmodernists might disagree). Alternatively, if it is thought that fictions are timeless Platonic abstract entities (sets of propositions, perhaps), we should say that which fictions we consider and express is a matter of human activity: and the ‘authors’ of those eternal Platonic fictions actually expressed have a good deal of control over which of a variety of such fictions they express. However, "theoretical fictions" introduced as an alternative to realist theories, and which are supposed to play a serious role in inquiry, do not seem to be able to be as arbitrary. Not any old story told about possible worlds will serve as the modal fiction, at least if it is to provide the heuristic and other advantages of talk about possible worlds. The suspicion is that in some respects talk of possible worlds cannot be like paradigm fiction, since the ‘choice’ of which story about possible worlds should count as the modal fiction is not as up to us as what to say about Sherlock Holmes was up to Conan Doyle.[6]

Modal fictionalists can certainly respond to the more general worry that fictionalism makes it too arbitrary which particular story about possible worlds ought to be employed. After all, the purposes of the fiction constrain what sorts of fiction are suitable, just as not any old story about a gas will serve to provide an "ideal gas" which has a behaviour approximated by real gases. Some story must be told about what sorts of constraints are appropriate, and why: and this can be difficult in its own right (see the "which fiction should be employed" section, below). Even if there are substantial constraints on what story will be adequate, and these constraints are not due merely to facts about us or our choices, there may still be some scope for the story to be artificial to a small degree, for some points of detail may be left underdetermined by the constraints. This may also be considered a problem, but it is unlikely to be fatal.

There is a more specific worry that remains even if a suitable account of what constraints there are on the modal fiction can be given. This is that it is too contingent a matter whether there is a modal fiction at all. After all, if there had never been any sentient creatures, no stories would ever have been told, and even if the modal fiction is construed as a Platonic entity (a collection of propositions, perhaps), it may never have been a fiction if it was never expressed by story-tellers. (Of course if nothing hangs on whether or not it is a fiction, then this will not worry the Platonist modal fictionalist). This worry, again, is particularly pressing if modal truth is to depend on the contents of the fiction, since it does not seem that whether or not blue swans are possible, for example, depends on whether or not anyone ever told stories. There are responses to this worry, and responses to these responses: it is suggested that the interested reader consult (Nolan 1997a).

4.2 Incompleteness

Fictions are often incomplete: they are silent about some issues. The Sherlock Holmes stories make no representation one way or the other about the exact population of India, or whether the number of hairs on Dr Watson's head is odd or even. Arguably, the modal fiction will be incomplete too: there will be some propositions such that neither they nor their negations will be true according to the fiction. This prospect raises several worries.

First, there is the "incompleteness problem" discussed by Rosen in Rosen 1990, pp. 341-345. There are some modal issues (and corresponding issues about the nature of possible worlds) that a realist may well be silent on: not because they believe there is no answer, but rather because they believe themselves ignorant of the answer. A fictionalist who treats the realist's theory as a fiction, on the other hand, will be silent upon the same issues - but this can lead to a more serious problem. If the fiction is silent on an issue (Rosen's example concerns the size of worlds), it is not that the issue is unknown -- it is that the fiction does not represent a fact of the matter one way or the other. So it might appear for the fictionalist there is not an unknown modal fact - either the claim is false because the corresponding worlds-claim is not true according to the fiction, or something involving a truth-value gap is going on. Rosen also discusses what effect this might have on modal claims corresponding to such silences. A detailed discussion and critique of Rosen on this issue can be found in the following supplementary document:

[Supplementary Document: Rosen's Incompleteness Worry]

What is uncontentious is that modal fictionalists operating with fictions which are incomplete in the way, e.g., that the fiction of Rosen 1990 is, will face difficulties, or at least departures from orthodoxy which will be found unattractive by some.

Another "incompleteness" worry in the literature is that expressed in Nolan 1997a. This is also a worry that the modal fiction will not represent as much as is desirable, though the concern is not confined to those areas in which realists might confess ignorance. (The concern resembles an objection Lewis brings against "sparse linguistic ersatzism" in Lewis 1986, pp. 142-165.) A modal fiction, to be adequate, must represent a very great deal about possible worlds, since there are infinitely many claims about possible worlds that must be part of the content of the fiction if there are to be enough possible-worlds claims to correspond to all the modal claims we would accept. Only a tiny proportion of the propositions about possible worlds needed will be able to be stated explicitly by the modal fictionalist: constraints of time and space and publication costs will mean that the fictionalist will need to describe the fictional worlds in only a few volumes, while an exhaustive explicit description of even a single possible world as complex as our actual world is beyond our finite resources.

What modal fictions will presumably have, however, are generalisations about possible worlds: for instance, principles of recombination and plenitude, principles about what truths are respected by all worlds, and so on. The modal fictionalist might reasonably hope that these generalisations *imply* all of the specific claims needed by the fiction. Implication is, however, a modal notion: not that this is automatically a problem, but it will be a problem for the "strong" modal fictionalist, who seeks to reductively analyse modality in terms of what is true according to the fiction. The strong modal fictionalist's analysis will be circular if he has to appeal to something like implication (or related modal notions) to spell out what claims are represented as true by the fiction, as it seems he must if the bulk of the claims are to be represented only implicitly. It seems that a strong modal fictionalist will be stuck with a radically incomplete fiction, if he relies only on what his modal fiction explicitly says, or he faces the task of specifying the implicit content of the modal fiction without recourse to modal notions like implication.

A strong modal fictionalist could attempt to capture non-explicit content in ways that did not rely on modal resources: one way this could be attempted would be to offer a syntactic account (or some other non-modal account) of some sort of consequence relation, and to stipulate that the fiction is to be considered closed under the relation thus specified. However, this is not easy to do in such a way that all of the necessary semantic consequences are indeed "consequences" of the explicit generalisations given. Furthermore, success at this project threatens to undermine the strong modal fictionalist's project in another way: for if it was possible to give a specification of a relation of "consequence" without relying on primitive modal notions, and that did the work of semantic consequence, then this would offer an analysis of "broadly logical" consequence (and presumably related notions, such as logical necessity and possibility) directly, rather than in terms of what was true according to a modal fiction, thus making the strong modal fictionalist's analysis of modality in terms of the fiction redundant. So the strong modal

fictionalist faces a serious challenge in providing a fiction capable of representing what is needed for his theory to be adequate.

4.3 Which Fiction Should Be Employed?

An essential part of an adequate modal fictionalist theory is a specification of the fiction of possible worlds which is to be employed. As well as selecting one of the many potential candidate stories about worlds, it is also essential to provide an explanation and justification of the choice. This is very rarely done by modal fictionalists (Armstrong 1989 provides an exception). This is not to say that it cannot be done, or cannot be done plausibly: but justifying the choice of fiction is not something that can be neglected if a modal fictionalist theory is to be convincing.

As with so many other challenges, timid modal fictionalism can immediately provide the outlines of an answer to this question. (Though it is to be remembered that timid modal fictionalism is able to avoid so many theoretical difficulties only because the fiction is not asked to do much theoretical work). If the truths of possibility and necessity (and conditionality, and other modal truths) obtain without dependence on the content of the modal fiction, it is surely reasonable to suppose that whichever fiction it is correct to employ, it must respect those independently obtaining modal truths. Strong modal fictionalists must also ensure that the contents of the fiction are associated with the modal claims they wish to make in the appropriate way, of course, but this will be of less help to them in establishing the content of the modal fiction. For if the content of the modal fiction is to explain the truth of the modal claims, it must be able to be fixed independently, on pain of circularity. This is especially so if the strong modal fictionalist holds, as one well might, that it is our understanding of the modal fiction that provides (perhaps implicitly) our epistemic access to which modal claims are true and which false. Giving a non-circular specification of the content of the modal fiction is one of the very difficult challenges facing the strong modal fictionalist.

While strong modal fictionalists cannot appeal to an independently constituted body of modal truths, one thing they can do is insist that the modal fiction respect our ordinary modal *judgments*: that is, that by and large if we *accept* a modal claim as true, the associated claim involving possible worlds will be true according to the modal fiction. (Rosen 1990, p. 337, speaks of the desideratum that modal fictionalism "*ratify* a substantial body of prior modal opinion".) This is presumably not to forbid any departures from our pre-theoretic modal judgements, should they be required, but it would provide a way even for the strong fictionalist to rule out gratuitous departures from our modal opinions.

The next obvious source of content for the modal fiction is the literal truth about our actual world (Rosen 1990, p. 335). The addition of all literally true non-modal propositions (in a suitable sense of "non-modal") to the fiction as part of its description of the actual world is useful, since it provides a rich source of content that can be extended by, for instance, a principle of recombination, to yield claims about non-actual worlds. It would also seem to be required, for if the fiction fails to be committed to the actual world verifying a certain non-modal truth *q*, the inference from *q* to Actually-*q* and back will be jeopardised. Some particular non-modal truths may prove especially useful: Armstrong 1989 pp 138-139

mentions analytic truths, truths in virtue of the meanings of terms, in this connection. One can either add the actual-world non-modal content by including an "encyclopedia" in the fiction, as Rosen does, or one could allow it in by, for example, stipulating as extra bridge-laws biconditionals of the form:

P iff According to PW, at the actual world, P

for all non-modal propositions P.

As well as conformity with our pre-theoretic modal judgements and inclusion of an encyclopedia of actual non-modal truths, Rosen 1990 mentions another source of information to apply in specifying the modal fiction. We have practices of forming modal beliefs involving imagining situations in accord with principles of recombination, non-arbitrariness, and so on (p. 339-40). Rosen points out that while a realist has the challenge of explaining why this practice of imagining should be a guide to modal truth, the fictionalist need not face this challenge if those practices are part of the process of constructing the fiction of possible worlds. If the constraints, or limits, on our imaginative practices when considering hypothetical situations are vital in our practice of making many of our modal judgements, it would make sense to similarly constrain the modal fiction.

There are no doubt many other sorts of constraints which a modal fictionalist may appeal to in order to narrow down the class of fictions about possible worlds which are acceptable for her purposes. Even after all of these constraints are in place, however, there may still be the theoretical possibility that more than one fiction about possible worlds (complete or incomplete) satisfies them equally well. A fictionalist facing a choice between equally deserving fictions would need to address the issue of what attitude to take to other modal fictionalists who choose differently. (Should they be judged incorrect? Correct, because judgements about the content of the modal fiction are relative to which (acceptable) fiction is adopted? Or should they be judged to be talking about something else?). Or perhaps the fictionalist could find some way to avoid making the choice of one single fiction.

If the fictions disagreed sufficiently, there may even be fictions which meet the constraints but which differ on matters which are linked through the fictionalist’s biconditionals with literal modal claims. (This is only possible if the modal truths themselves are not being appealed to as constraints on acceptable fictions, so is not a problem which faces the timid modal fictionalist). If the constraints are not enough to uniquely determine the truth-value of every modal claim, then not only the determinacy of the content of the fiction but the determinacy of the truth-value of some modal claims is at stake. Are those modal claims true or false, or neither? Might they be fiction-relative, so there are no-fault disagreements about them?

This is not the place to attempt to settle the matter of whether constraints are likely to uniquely determine a modal fiction, nor whether it would be genuinely objectionable if they did not do so. Rather, the issues are mentioned as ones to be kept in mind when formulating or defending a modal fictionalist theory.

4.4 The Theoretical Primitives of Modal Fictionalism

Metaphysical theories often rely on resources which are taken as "primitive": roughly, theoretical resources which are not to be further explained or analysed. Different theories of the same subject matter will often take different resources to be primitive, and while it is a difficult question to decide whether one set of primitives is better or worse than another, evaluation of the relative simplicity, naturalness, or other merits of theoretical primitives is part of the evaluation of rival theories. This sort of comparison can can be especially relevant in areas where disputes between rival theories are not to be settled easily by experiment or observation. Such disputes make up one of the battlegrounds between fictionalists and their rivals, with anti-fictionalists claiming that the unanalysed theoretical resources which fictionalists rely on render fictionalist theories unattractive, or at least relatively unattractive compared to some rival or other.

The central piece of theoretical machinery the modal fictionalist employs is the "According to PW ..." operator. When it is glossed in tempting ways, as "if PW were true, then ..." or "it follows from PW that ...", it seems to be a modal notion: and if this is not to be further explained, the modal fictionalist cannot use the fiction of possible worlds and its contents as the basis of a reductive analysis of modality. This will only be of concern to some modal fictionalists, of course -- timid fictionalists will not have been looking for a reductive analysis of modality based on their fiction in the first place - and some timid fictionalists such as Divers 1999b explicitly endorse modal explanations of the fictionalist operator (Divers 1999b p 335). Such fictionalists may be happy to take advantage of possible analyses of "according to the fiction" operators in modal terms, and in so doing provide an answer to the question of how to understand such expressions: but on the other hand, their position may not be attractive to someone primarily concerned to analyse modal operators. (Even timid fictionalism is compatible with a reductionist account of modality, of course, since the timid fictionalist may seek to explain modality in some other terms. It is just that it is not hospitable to reductionist accounts of modality in terms of possible worlds).

A fictionalist who wishes to provide an analysis of modality, on the other hand, had better not take their "according to PW ..." operator to be analysed in terms of standard modal devices, or alternatively in terms of possible worlds (see Rosen 1990, pp. 344-345). The canonical version of the theory that Rosen presents takes the "According to PW ..." operator to be a primitive one: that is, one which is not to be further analysed, in modal or non-modal terms (Rosen 1995, p. 70). Rosen points out that one might think that his favoured prefix is a modal locution, and if so even his position cannot be said to entirely reduce the modal in favour of the non-modal (Rosen 1990, pp. 344-345). Nevertheless, as he points out, it may still be thought to be some theoretical advance to be able to explain all of the other modal notions using only this one. It is hard to know how the issue of whether or not "according to PW.." should count as a modal operator is to be decided: in any case, it will not be further pursued here.

Regardless of its status as a modal locution, Rosen recognizes that it is a very unsatisfying primitive: the notion of a proposition being true according to PW is an unlikely one to be considered basic and unanalysable. Whether or not this is a fatal flaw of Rosen’s proposal is, he acknowledges, "a matter of somewhat delicate judgement" (Rosen 1990, p. 349). What he does have to say about it, however, is that arguably many realists about possible worlds have also not provided a satisfactory analysis of the

"according to the fiction ..." operator, and so face the same challenge.[7]

The issue of whether "According to PW..." is a satisfactory theoretical primitive is presumably partly to be settled by seeing what rival theories are possible, and what primitives they need to rely on to account for modality and for fiction. Beyond that, how to settle disputes about the relative attractiveness of primitives is a difficult issue in philosophical methodology. Taking such an apparently complex operator to be unanalysable looks unattractive (Nolan 1997a, pp. 273-274), but the position is perhaps not untenable. A better option for the modal fictionalist interested in analysing modality in terms of the modal fiction might be to attempt a non-modal explanation of what is true according to fiction. In any case, this problem, like many problems for modal fictionalism, does not arise for the timid modal fictionalist. For those fictionalists for which it is a problem, however, the unattractiveness and unintuitiveness of taking "According to PW..." or a similar device to be primitive remain a largely unaddressed challenge.

4.5 The Threat from Abstractionism

For modal fictionalism to become the preferred treatment of possible worlds, it must not only be able to perform adequately the tasks assigned to talk of possible worlds, it must also do better than its rivals, or at least possess virtues that those rivals lack. However, modal fictionalism faces a close rival that apparently shares its benefits and avoids some of its vices. Instead of a fiction of possible worlds, some rival views identify possible worlds with certain maximal representations. This sort of "abstractionist" view (following the terminology of Van Inwagen 1986), or "ersatz" view (in the terminology of Lewis 1986) is prima facie committed only to representations, as a modal fictionalist must it seems also be, but the abstractionist is a realist about possible worlds, and thus has prima facie a more straightforward approach than the fictionalist's.

This is particularly true in the case of the platonist modal fictionalist. If the modal fictionalist accepts that the modal fiction is a collection of platonistic propositions, then that very collection of propositions will also do as an abstractionist's "world book": and if the fiction provides a separate description of each possible world (or such a description can be constructed from the resources given), then these complete representations will just be those things which some abstractionists take to be possible worlds. A modal fictionalist may be driven to accept that the fiction is a collection of propositions in response to any of several objections: the worry about artificiality, the worry about incompleteness, or alternatively on more general grounds (given that taking fictions to be collections of propositions is attractive quite apart from considerations about modal fictionalism). (This worry is mentioned in Nolan 1997a p 272.)

Suppose that a modal fictionalist does accept an ontology of propositions rich enough to provide for maximal consistent collections of such propositions. Why then would fictionalism be preferred to abstractionism, or vice versa? Abstractionism would have the advantage of being a more straightforward treatment of normal quantification over possible worlds, since there would be no need to suppose that there is (or should be) a silent "according to the fiction of possible worlds" or "according to the presupposition that there are worlds" governing such possible-worlds talk. Nor would abstractionism face

the technical challenges that fictionalism faces, since all the merely possible worlds would in fact exist; there would be no problem of switching back and forth between fictional and literal discourse. Furthermore, an abstractionist would not need to face the worries of accounting for the "according to the fiction..." operator: the abstractionist's overall theory would need to make room for this operator somewhere, but she could hold out the promise of being able to use modal locutions and talk of possible worlds in its explication without risk of circularity.

One reason that might be offered for preferring modal fictionalism to some form of abstractionism is that abstractionism faces a battery of well-known objections, levelled against it by Lewis 1986, chapter 3. (Rosen 1990 p 328-9 mentions this as a motivation for fictionalism against abstractionism.) It is far from clear that fictionalism avoids these objections, however: and it seems that fictionalism committed to Platonic propositions prima facie faces the same worries about representation, primitive modality, and mysterious ontology. Whether the abstractionist can answer Lewis's objections, and whether the fictionalist can answer or avoid them as well or better, is an issue beyond the scope of this entry. I merely note that the Platonist fictionalist in particular should be cautious in drawing too much comfort from these arguments.

Rosen 1990 suggests another reason. It might be thought that there are good arguments to show that possible worlds, if there are any such things, must be concrete cosmoi like the one in which we inhabit, and cannot be abstract objects, especially abstract objects like collections of Platonic propositions. (He assumes that this has been established for the purposes of his paper on p. 329.) Indeed, if there were arguments to show that collections of propositions were non-starters as candidates to be possible worlds, this would damn the project of abstractionist theories of this form. It is hard to find in Lewis, or elsewhere, arguments that our conception of possible worlds is so tied to their being concrete that we should prefer to believe that there were no merely possible worlds than to believe that they turn out to be abstract objects, however, though Armstrong 1989 (p 46, 49) offers this as a reason for being a fictionalist rather than an ersatzer (abstractionist).

Finally, a modal fictionalist might reject abstractionism because he rejects the associated ontology. This move does not seem open to a Platonist modal fictionalist, since the ontology is one of collections of propositions in both cases. A non-platonist fictionalist, who is happy to rely on fictions construed as collections of marks on paper, or noises in air, or perhaps a combination of these and mental states of speakers and listeners (or writers and readers), can then reject the abstractionist accounts of possible worlds at issue precisely because they are committed to abstract representing entities. Such a fictionalist needs to deal with the worries about artificiality and incompleteness (see above), which arise in more acute forms than face the platonist. He also has a further difficulty in that many accounts of fiction themselves refer to propositions, and are committed to them. The fictionalist who eschews propositions will need to provide an account of fiction and of sentences being true according to fictions compatible with repudiating commitment to propositions. This is not an easy task. However, if it could be carried out, it would be clear that in one respect at least - the respect of ontology - the fictionalist would have a theory with definite advantages over abstractionism. Since ontological concerns are among the primary motivations for modal fictionalism, this is no doubt a path some modal fictionalists will attempt.

4.6 Does Modal Fictionalism Deliver Possible Worlds Semantics?

John Divers in Divers 1995 argues that modal fictionalism cannot deliver the benefits of the standard possible worlds semantics for modal discourse. There is a discussion of Divers's argument in the following supplementary document:

[Supplementary Document: Modal Fictionalism and Possible Worlds Semantics]

4.7 Concern about Concern

Another worry about modal fictionalism is discussed by Rosen 1990 (pp. 349-354): the "argument from concern". An "argument for concern" was originally developed as an objection to the (realist) theory of possible worlds proposed by David Lewis. Lewis claimed that the truth of counterfactual conditional claims could be analysed as the truth of claims about the goings-on in other possible worlds: to take the classic example, the claim "Hubert Humphrey might have won" is true because there is a possible world very similar to ours in which someone much like Hubert Humphrey *did* win. Saul Kripke in Kripke 1980 suggested in a footnote (p. 45) that there was a problem for this view: while Humphrey cares a great deal about the fact that he might have won, he presumably does not care about whether someone a lot like him but who is not him wins in another cosmos. ("Probably, however, Humphrey could not care less whether someone *else*, no matter how much resembling him, would have been victorious in another possible world"). In any case, it is hard to believe that his concern about the first fact is a concern about the second. Examples can of course be multiplied: we often care about modal features of our lives (what could have been, and what would have been), but non-philosophers perhaps seldom even think about whether people much like them have different experiences in different cosmoi, let alone care deeply about such things. So expanded, the "argument from concern" is that the analysis of the truth-conditions of modal statements about objects in our world turns matters we care about into matters we do not care about, and so fails to be a plausible analysis. (Note that Kripke himself does not expand his passing comment in this way).

The analogous "argument for concern" can be run for modal fictionalism (and indeed for almost any account of the truth-conditions of modal claims: see Lewis 1986, pp. 195-197, who argues in part that ersatzers are in the same boat as he is). Humphrey cares about whether he could have won the election, or whether he would have won if some things had been done differently, but it is hard to believe that he cares particularly whether according to a certain story people like him win in other worlds, or even whether according to a certain unusual story he himself wins in other worlds. So it seems implausible to suppose the question of whether or not he could have won is the same question as the question of whether according to the story he does win in certain other worlds.

As Rosen points out in the case of Kripke's objection to Lewis, "this by itself is not a logical objection to the claim that the facts are identical" (p. 349). One may care deeply about something, not realising that it is identical to something else one claims not to care about (just as I might greatly admire the speeches of Cicero, and honestly claim to have no time for the speeches of Tully). Even if the issue of whether

Humphrey could have won is just the issue of whether the modal fiction says that counterparts of Humphrey win at other worlds, this would not mean that this philosophical analysis will be obvious to workaday politicians like Humphrey, nor need it be reflected in his views. Rosen suggests that the objection might have a more ‘pragmatic’ force (p. 350). The objection might be something like this (the way of putting it is not Rosen’s, but I take it the sentiments are): we care about what might have been, and if the modal fictionalist is right, what might have been is a matter of what the fiction says about what goes on in other worlds, and what some complicated story says about other cosmoi is not something we currently have more than an academic interest in, it seems. So if we accept this theory, we should revise what we care about (since we shall think the two come to the same thing): either by becoming as indifferent to modal matters as we are to what story the modal fiction tells - or alternatively by becoming as concerned about the contents of the modal fiction as we currently are about what could have been and would have been, had we acted differently. Either option requires large revisions of our concerns, and it is a cost of a theory to require such revision.

Rosen’s response to this, on behalf of the modal fictionalist, is that this price is worth paying, particularly if we extend our concern to the contents of the fiction, rather than the much harder task of ceasing to care about modal matters of fact. He then goes on to point out that this raises another worry, that of arbitrariness: why care so much about the contents of the modal fiction as opposed, say, to any other story about many worlds and what happens in each? Rosen discusses several possible replies to this question (pp. 352-353), though leaves the final answer open. It seems to this writer, however, that this might not be a particular problem for modal fictionalists: for the question of why we should care about modal facts as opposed to truths expressed with any other conceivable intensional operators looks equally pressing, and any realist who, for instance, analyses modality in terms of the nature of possible worlds will face the question of why we should care about what is true according to the various worlds, as opposed to what is "shtrue" at these worlds, where the "shtrue at" relation is some other relation between worlds and propositions. At the very least, one would want a theory of how our concern for modal truths might be justifiable before seriously worrying about whether the same sort of thing could be said about concern about the content of the modal fiction.

Finally, the whole argument from concern presented above only really gets a hold on the modal fictionalist who thinks that what is the case modally is just a matter of the contents of the modal fiction. There is no need to think this, of course, and timid modal fictionalists will reject it. (Rosen also points out that the modal fictionalist can sidestep the argument if he does not take the fiction to provide the materials for an analysis of modality.) Even strong modal fictionalists can in principle think that there is some sort of analysis or reduction of the modal to what the contents of the fiction are without taking the further step of thinking that the modal facts and facts about the content of the fiction are one and the same. (This would be one way of linking the two, but they might think that the modal facts are constituted by facts about the fiction without thereby being identical with them, for example). So the argument from concern creates problems only for some modal fictionalists.

Notes to Modal Fictionalism

Notes

1. Examples include cases where P itself contains nested modal locutions, or where it contains names or other rigid designators subject to counterpart-theoretic paraphrase.

2. Other biconditionals which might be needed besides the ones associated with the sentential operators of necessity and possibility are ones connecting counterfactual statements and "closeness" relations between possible worlds, and biconditionals connecting probability values and measures on sets of possible worlds. De re modality may call for even more biconditionals, linking de re modal claims to claims about which counterpart relations, or trans-world identities, hold according to the fiction.

3. A modal fictionalist need not take possible worlds to be concrete, spatio-temporal (albeit fictional) objects: one could easily be a fictionalist whose fiction of possible worlds describes them as being abstract objects of some sort. This "abstract object" approach has not received much support in print, however.

4. This blanket approach would require rejection of some widely held basic principles of modal logic: that "possibly P" is true whenever "P" is, for example, or that "actually P" is true for all true P (if "actually" is to be treated as a modal operator, as it often is taken to be). This view would also run into difficulties if we retain the standard interdefinition of "necessarily P" with "not-possibly not-P" and "possibly P" with "not-necessarily not-P". If both "necessarily P" and "possibly not-P" were without truth value, excluded middle would fail, since "possibly not-P or not-possibly not-P" would fail to be true. If statements prefixed with a modal operator were all treated as false, on the other hand, then if the standard interdefinitions applied, violations of the law of non-contradiction could be generated. One counterexample to non-contradiction could be derived from the falsity of "possibly not-P or not-possibly-not P". Since this is false, its negation is true (plausibly), and hence, by application of a De Morgan law, "not-possibly not-P and not-not-possibly not-P" follows, which is a contradiction. It is, of course, open to a fictionalist to reject both the basic modal inferences mentioned and the standard interdefinition of possibility and necessity. Such a theorist could still allow that these moves and the interdefinition preserve truth *according to the fiction of modality*, which may salvage enough of the basic principles and the interdefinition for a fictionalist’s purposes. ss

5. Jeremy Bentham, (Works VII 76-9, 1959, pp. 53-58) advocates fictionalism about the "qualities" of impossibility and possibility, as well as probability and improbability. It is clear that he understood these "qualities" as epistemic rather than alethic ones, but his general approach suggests he might have said the same about the ascription of alethic modalities. He would then count as an early fictionalist about

modality itself.

6. The concern is exacerbated if the fiction of possible worlds is intended to provide an analysis or reductive explanation of modal truth (i.e. if "strong modal fictionalism" is intended). For the modal truths are not up to us, it seems. Whether or not it is possible for it to be simultaneously raining and not raining (in the same location, at the same time, in the same respect, etc. etc.) does not seem to be anything we have any control over. Furthermore, some propositions being necessary and others possible, some de re modal claims being true and others false, does not seem to depend on whether or not humans bothered to tell stories about possible worlds. Finally, if things like natural laws and causation are modal matters (e.g. if causation is a matter of the obtaining of certain counterfactuals), the artificiality of modality would seem to imply that even natural laws and causation are, to some extent, artificial. This anti-realism will be found objectionable by many (though not by all: Rescher reasons from conceptualism about modality to idealism virtually across the board through these sorts of connections (Rescher 1975)). Taking modal facts to depend on accidents of our storytelling seems to make the modal truths too artificial.

7. Though Rosen does not say so in quite so many words, he seems to have particularly in mind David Lewis and the account of fiction he offered in Lewis 1979. Lewis's account of fiction is one in which what is true in a fiction is what is true in certain possible worlds determined by the text of that fiction. Rosen points out that such accounts would have trouble dealing with fictions about the space of possible worlds as a whole (Rosen 1990, pp. 345-346). If the realist's analysis of truth in fiction does not satisfactorily deal with what is true according to fictions like PW, the realist cannot claim to have an account of "According to PW..." that the fictionalist lacks (p. 346). So if Rosen is right, the realist cannot analyse away the locution that the fictionalist takes as primitive, so the realist cannot claim to be better off in choice of primitives. Rosen recognizes that the realist might eventually be able to account for even this class of fictions using possible worlds, and should that day come the realist will be able to reclaim the advantage of avoiding the "according to PW" primitive.

The sort of treatment offered by Lewis 1979 notoriously faces difficulties in dealing with impossible fictions more generally, especially ones in which it is not straightforward to divide the fictions into consistent subfictions. But there are world-based treatments of fiction that are arguably more successful at dealing with these problems: Routley 1990 (Ch. 7) is one example. Another way of developing a more adequate account of impossible fictions is to stay classical but supplement the theory of Lewis 1979 with impossible worlds (classical accounts of impossible worlds include Nolan 1997b and Zalta 1997, among others). So Rosen's *tu quoque* is shaky, at best. In any case, an analysis of fiction which relied in part on some modal resource or other need not look very much like the traditional approaches employing possible worlds, and it does not seem that Rosen has given us reason to suppose that such analyses of fiction could not be made to work.

Supplement to Modal Fictionalism

A Persisting Problem For Fictionalism About Possible Worlds[*]

At least since Gideon Rosen's 1990, the theory that talk about possible worlds should be interpreted as a useful fiction has been taken seriously by many philosophers as a way we might be able to have, in Lewis's phrase, "paradise on the cheap" (Lewis 1986, p. 136).

The point of fictionalism about possible worlds is that if it is successful, it enables one to use the conceptual resources of possible-world semantics without needing the ontological baggage that realism about such worlds carries. The strategy is to employ an account of possible worlds (e.g. David Lewis's)[1], but insist that the account is only a useful fiction. A modal claim will then be true iff its translation into possible-world semantics is true in the fiction (let us call the account treated as fiction by Rosen the "Lewis story"[2]). So, for example, P is possible iff, in the Lewis story, there exists a possible world where P is true. Of course, this does not imply that in reality there is a possible world such that P is true (at least as far as the fictionalist is concerned), any more than its being true in the Arthur legend that King Arthur defeated the Emperor Augustus implies that Arthur (if he existed) really defeated Augustus in battle.

A problem was raised for modal fictionalism independently by Rosen (1993) and Stuart Brock (1993). This problem, to put it in a perhaps oversimplified form, is that since in the Lewis story it is true at each possible world that there are many worlds, it is, *according to the fiction* (or, according to the story), true at every possible world that there exist many worlds. But the truth conditions offered by a Rosen-style fictionalist state that if according to the fiction a proposition P is true at every world, then P is (in fact) necessarily true. Therefore, it follows in this case that necessarily there are several possible worlds, and so since (necessarily P) implies P, there in fact exist several possible worlds, which is not something the fictionalist should countenance.

This problem is discussed in a paper by Peter Menzies and Philip Pettit (1994) who claim to show that the objection is not fatal, and that there is a coherent and plausible fictionalist way of avoiding it. Menzies and Pettit propose that the fictionalist operator needs to be applied to every quantifier in a modal claim when translating into possible-world talk, either by employing a "prefixing" strategy or an "indexing" strategy (for details see their paper). So while it is not true (for the Menzies/Pettit fictionalist) that "necessarily there exist several worlds", what is in fact true in virtue of there being several possible worlds that exist at each fictional world is that "necessarily, according to the fiction there exist several worlds", which is not a claim incompatible with fictionalism at all. However, they recognize a *further* problem for fictionalism: a problem involving a so-called "modal dangler", or a modal claim that

concerns the truth (or in this case, possible truth) of the theory itself.[3] This supplement will consist of a discussion of this problem, an examination of the solution proposed for it by Menzies and Pettit, and an explanation of why the proposed solution is so far unsatisfactory.

This further objection is more or less as follows: The Lewis story (or the "hypothesis of the plurality of worlds" (PW) as it is referred to by Brock and Menzies/Pettit) will, according to the Lewis story, be something that is true at every world in the Lewis story. This causes the modal fictionalist a real problem, because given the standard paraphrase into possible world semantics, something is necessary iff it is the case at every possible world. Since, in the Lewis story, the Lewis story is correct at every possible world, then the fictionalist who is prepared to translate modal claims into claims about possible worlds (albeit fictional ones) is forced to admit that the truth of the Lewis story is necessary, and thus the Lewis "story" is no mere fiction, but actually correct. (Necessarily-P implies P). However, it is precisely PW, or the Lewis story, that the fictionalist wants to argue is *false* in the actual world. It appears that the fictionalist (at least one who follows the strategy described) is committed to the truth, and even necessary truth, of the very thesis fictionalism was developed to deny.

Menzies and Pettit suggest an alternative way of constructing one's possible-worlds fictionalism to avoid any commitment to the necessary truth of the Lewis story. They start by pointing to the special status that the actual world has among worlds. Other worlds are (according to our fictionalist) purely fictional entities, so what is true at[4] them is completely determined by the fiction. What is true at the actual world, however, is not determined by what (modal-) fictional stories we choose to tell about it. The truth conditions for the "modal danglers" (statements concerning the modal status of the modal fictionalist theory itself) are to reflect this, on the Menzies-Pettit proposal. According to the proposed paraphrase for the part of modal discourse concerned with modal danglers,

> Possibly P if and only if ‘P’ holds at the actual world or at one of the other worlds in PW.
>
> Necessarily P if and only if ‘P’ holds at the actual world and at all of the other worlds posited in PW" (1994, p. 36)

Note that these truth conditions do not say "if ‘P’ holds in the actual world *on the PW account*". These truth conditions involve what the actual world is really like, and not merely what it is like in a given fictional account. Thus this view allows us to conclude that PW, or the Lewis story, is not necessary, and so we are not forced to admit that it is true.

This modification works to defuse Brock's specific objection about the expressibility of the falsehood of PW, but it does not defuse objections based on counterfactual situations where we would want to say that the Lewis story is not correct. For instance, consider the quite plausible counterfactual "If there were a king of France, still PW would be false". A fictionalist should want to accept this: after all, changes in the political situation in France will not produce changes in the fundamental truths of the metaphysics of modality (France is not *that* important). However, consider this modal claim: "It is possible that there be a present king of France and also that PW be false". Now, it is not true of the actual world that there is a

king of France, and it is not true of any of the (supposedly fictional) possible worlds that PW is false there (after all, in the Lewis story, the Lewis story (or PW) holds at every world). The above modal claim about the king and PW is thus false. For a counterfactual with a contingent antecedent to be true it must be possible that the antecedent and consequent be true together. Since it is impossible that there be a king of France and PW be false, it seems that the initial plausible counterfactual cannot be held to be true by the fictionalist.

This sort of objection, of course, is a general one: nothing hinges on the mentioning of the present king of France, as almost any counterfactual will do. The general point is that a fictionalist should be committed, on the grounds of the irrelevance of most changes in the world to the truth of fictionalism, to saying that even if the world had turned out slightly differently, still the Lewis story would have been merely fiction: and this is something that cannot be coherently maintained by a fictionalist who accepts the Menzies/Pettit truth conditions for modal statements.

One might be tempted to think that the entire problem of the modal status of modal danglers (i.e. those statements that concern the truth or modal status of the theory itself) is one that can be ignored, or at least easily avoided, by the fictionalist. After all, the modal danglers are a pretty special class of truths, unlikely to make an impact on science or semantics or other fields in which possible worlds are useful. One way of avoiding the problem of "modal danglers" is to restrict fictionalism so that it does not consider the modal status of the theory itself, but that the theory functions as some sort of "metalanguage" immune to the modal interpretation available for all other areas of discourse. There are at least two good reasons for resisting this strategy, however.[5]

Firstly, it seems *ad hoc*. Possibility seems to be the same thing in both the sentences "Possibly PW is false" and "Possibly Phlogiston Theory is false": merely using the word "metalanguage" does not provide explanatory power. Secondly, it leaves the "possibly" operator in modal danglers as a primitive. If we are going to have primitive unanalyzed modalities besides that of "truth in fiction" in our theory anyway, why bother with an analysis of modality in terms of truth-in-fiction? Why not say that all of the modal operators reflect primitive features of the world and abandon the attempt to analyse modality in terms of a modal fiction?

It is too early to say that a Rosen-style modal fictionalism must be abandoned -- after all, merely showing that it has not yet succeeded in analysing the full range of modal claims (e.g. modal danglers) does not imply that it cannot do so, but only that it has not. However, even given the Menzies/Pettit modifications to Rosen's original proposal, modal danglers remain a difficulty for modal fictionalism. Those eager to promote fictionalist analyses of possible worlds talk owe us an answer to this problem.[6]

Notes

[*] Another version of the central objection in this piece to the Menzies/Pettit proposal has been developed independently by David Lewis.

[1.] This is the account of possible worlds that is treated as the fiction about possible worlds by Gideon Rosen, (1990) and by Menzies and Pettit (1994), and by Brock (1993).

[2.] I prefer to use the term "Lewis story" it when discussing the specific proposal that takes Lewis' theory as the fiction rather than using the term "PW" or "the fiction of a plurality of worlds", as obviously one could employ a story about the existence of many possible worlds without it agreeing with the story told by David Lewis. (One could have trans-world identity rather than counterparts, for example).

[3.] See Menzies and Pettit (1994), p. 35, for this "Last Difficulty". They attribute this further objection to Stuart Brock.

[4.] At_1, for those who wish to be precise in the manner described in Menzies and Pettit (1994), p. 33

[5.] These reasons for rejecting this move are the same sorts of reasons that Brock (1993, pp. 149-150) outlines for not arbitrarily ruling "Necessarily there are many worlds" out of consideration by a fictionalist theory.

[6.] I am especially indebted to Peter Menzies and Philip Pettit for encouragement as well as helpful comments and discussion.

Supplement to Modal Fictionalism

Rosen's Incompleteness Worry

The "incompleteness problem" discussed by Rosen (1990, pp. 341-345) can be expressed as follows: there are some modal issues (and corresponding issues about the nature of possible worlds) that a realist may well be silent on -- not because they believe there is no answer, but rather because they believe themselves ignorant of the answer. A fictionalist who treats the realist's theory as a fiction, on the other hand, will be silent upon the same issues -- but this can lead to a more serious problem. Rosen, who uses as his fiction the theory that David Lewis proposes as fact, takes as an example an issue Lewis 1986 is silent on: the maximum "size" of possible worlds (or in particular, the maximum number of non-overlapping physical objects in a single world). Rosen's worry is this: according to the view he develops, (the numbering is Rosen's, and the details are from his example on p. 342 of 1990):

> (10) There might have been κ non-overlapping physical objects.
>
> if and only if
>
> (10f) According to PW, there is a [world] containing κ non-overlapping physical objects.

(10f) is not true, since PW is silent on the issue. So (10) is not true. But the same thing happens for the negation of (10):

> (11) It is not the case that there might have been κ non-overlapping physical objects.
>
> is plausibly true if and only if
>
> (11f) According to PW, no [world] contains κ [non-overlapping] physical objects.

If (11) is really the negation of (10), then classically one of them must be true. If one of them is literally false, then its negation should be true. Rosen is inclined to accept (on the fictionalist's behalf) that they are genuine contradictories, and both lack a truth-value. He points out, however, two difficulties with this: firstly, his proposal makes (10f) and (11f) truth-valueless too, when they seem clearly false (at least if "according to PW.." works like "according to the fiction ..." operators standardly do); and secondly, the disjunction of (10) and (11) is true and a logical truth, so we have the truth of a disjunction without the truth of either disjunct. (Not that this is unknown in the treatment of truth-value gaps, as Rosen points out.) Such logical revision might be thought a high price to pay.

In addition, Rosen rightly points out (p. 342), the fictionalist has settled the question of whether it is true that there might have been κ many non-overlapping physical objects: it is not true. Those who were inclined to think that we are in ignorance of this piece of modal information (or any other piece of modal information about which the story is "silent" in a similar way) will not like this result. The fictionalist does not make room for modal ignorance to the same extent the realist does.

Rosen's discussion of this worry is unhappy in several places. The first is that (11f) is not his only official translation of (11), assuming "might have been" is to be treated as "possibly" in this context: controposing his biconditional for possiblity (with the appropriate substitutions for P) yields:

> It is not the case that there might have been κ non-overlapping physical objects
>
> if and only if
>
> (11f*) It is not the case that, according to PW, there is a world containing κ non-overlapping physical objects.

(11f*) yields the result that (11) is simply true, if we interpret "according to PW" in the usual way (and not the way which makes "According to PW, Q" truthvalueless if Q is "not determinately settled as true or false by the theory PW", whatever that might mean in this context). Since (11) *is* the contradictory of (10), and (10) is false by the lights of Rosen's original proposal, this should not be surprising. This result has unpleasant consequences of its own, of course, since accepting this theory would commit one to denying the interdefinability of possibility and necessity. Normally, "possibly P" is taken to be equivalent to "not-necessarily not-P", and "necessarily P" is taken to be equivalent to "not-possibly not-P". But the second will fail in this case (and the first will fail in other similar cases). For (11f) is the appropriate correlate of the claim that "necessarily, there are not κ non-overlapping physical objects", and this claim is standardly taken to be equivalent to (11). For the reasons Rosen gives, however, the correlate of (11f) is not true, whereas (11) is, due to the truth of (11f*).

Denying the interdefinability of necessity and possibility in the standard way is perhaps not as big a modification to our logic and semantics as introducing truth-value gaps. It will still be seen as very unattractive by many. There is another modification to the basic theory which might be made to deal with these cases, which is a different way of implementing the spirit of Rosen's proposed strategy here. Rosen says the fictionalist can modify his theory by "declaring that in general when the paraphrase P* of a modal claim is not determinately settled as true or false by the theory PW, the modal claim P is to lack a truth-value" (p. 343). What is puzzling about Rosen's implementation of this proposal is that he takes it that this implies that the "According to PW, P*" claim has to be truthvalueless when PW neither says P* or its negation. This has the further unwelcome consequence that "According to PW" will not function like "according to the fiction..." operators are standardly thought to. A more natural way of going, surely, is to treat "According to PW ..." in the standard way (i.e. it is just false that "According to PW, P*", when PW is neither committed to P* or to its negation), but to provide for truth-value gaps for the modal claims by restricting the fictionalist biconditional. Instead of the general scheme:

> P iff According to PW, P*,

the fictionalist could instead accept the clumsier:

> if P, then According to PW, P*, and if not-P, then According to PW, not-P*, and if According to PW, P*, then P, and if According to PW, not-P*, then not-P

and further stipulate that P is truthvalueless iff neither according to PW, P*, nor according to PW, not-P*.

When the fiction says something about whether or not P*, which will be the usual case, this longer set of conditions will permit the fictionalist to move back and forth from modal language to talk of possible worlds in the usual way: it is only when PW is silent about the relevant issue that the corresponding modal claim suffers a lack of truth-value. In modifying the central biconditional, it is true that the fictionalist is sacrificing some of the elegance of the original theory, though the unpleasant looking list of conditions can be rewritten so that they have more of the appearance of a minor alteration of the original:

> P iff According to PW, P*, (unless PW is silent about P*, in which case P is truth-valueless).

This still has the feature that a disjunction may be true without either of its disjuncts being true, and other features common to many treatments of truth-value gaps, and it still has the feature that the theory delivers definite answers of a sort for certain modal matters (i.e. that P has no truth-value) when it might have seemed that we imagined we were merely ignorant: it is still an approach with many of the features of Rosen’s amendment. It however lacks the most objectionable feature possessed by Rosen’s proposal of keeping the biconditional intact and declaring that "According to PW ..." is gappy.

In any case, Rosen’s incompleteness worry arises only for those modal fictionalist theories which do indeed admit that the modal fiction is silent on some relevant issues. Some are indeed likely to (and Rosen’s is one), but it should be remembered that this does not seem to be an unavoidable feature of such theories. One could attempt to specify enough about the content of the modal fiction so that it settled, at least in principle, all of the relevant issues. (It may be difficult to tell how they are settled, of course, if the content of the fiction depends, e.g., on facts about the arrangement of the actual world, but this is not a problem of completeness, but only of modal epistemology). In particular, timid fictionalists can stipulate the content of the modal fiction in terms of the modal truths (so, e.g. the fiction is to represent that at some world, Q*, just in case possibly Q). This sort of specification would only be circular if the status of the modal truths was to be analysed in terms of the content of the fiction, but the timid fictionalist has no such pretensions. While the timid fictionalist’s fiction may leave some questions unsettled (how many indiscernible worlds there are, for example), the timid fictionalist should be able to make the fiction determinate to the extent that all of the correlates of modal claims are represented, by brute stipulation if necessary. It may be harder for a strong modal fictionalist, but it has not been shown to be impossible.

In summary, then, while Rosen's incompleteness concerns may well not give rise to the problems he alleges, there are difficulties (or at least departures from orthodoxy) which will be faced by fictions which are incomplete in the sorts of ways that, for instance, Rosen's candidate is.

Supplement to Modal Fictionalism

Modal Fictionalism and Possible Worlds Semantics

John Divers in (Divers 1995) argues that "Modal fictionalism cannot deliver possible worlds semantics" for modal logics. Since Kripke, it has become standard to do the formal semantics for languages with modal operators (like necessity and possibility operators) by providing models of worlds and of objects in those worlds, and counting modal statements as true according to the relevant models if the worlds in those models meet certain conditions (e.g. where *p* is an atomic claim, "necessarily *p*" is true at a world *w* in the model just in case all of the possible worlds "accessible" from *w* are worlds at which *p* holds). On one construal of what benefits this sort of semantics offers, modal fictionalism arguably cannot do as well as its realist rivals.

The first thing that must be done is to be clear on what is meant by "possible worlds semantics". There is a common useage of that expression in which providing such a "semantics" for e.g. a language containing modal operators is a matter of providing certain sorts of semantic models for it. Formal specifications of these models can provide the basis for exploring the formal features of the system (such as whether it is decidable, or whether the consequence relation for the system is compact). Another benefit is that by specifying models with respect to which the axioms and rules of the system are demonstrably complete, we provide a mechanism for producing counter-examples (counter-models), as well as another method, besides e.g. an axiomatic proof procedure, for seeing what conclusions we might be able to draw from a given premise set. The capacity for constructing counter-examples is very important, since we are often as interested in which arguments turn out to be invalid as in which arguments are valid. Historically, providing "world" models for modal logic was also useful for bringing out dimensions of variation among modal logics: by putting various constraints on the accessibility relation, the behaviour of the necessity and possibility operators could be varied in ways it was hard to imagine before possessing the device of models.

However, none of these benefits require possible worlds *per se*, even for so-called "possible worlds semantics" in this sense (see Lewis 1986, pp. 17-20). The formal semantics officially consists of constructing models using sets of various kinds and functions from those sets to propositions or sentences (or other objects representing propositions or sentences: other sets do nicely). Certain objects in these models are often called "worlds", but this is just a convenient label: the blander word "indices" is sometimes recommended by logicians wanting to avoid the appearance of trucking with metaphysics. Interpreting a formal language with modal operators as having its truth conditions given by which indices stand in which relations need not bring possible worlds in the full-blown sense into the picture at all, any more than the models of modal logics that define truth in terms of geometrical features of cylinders commits users of these logics to the belief that there are special modal cylinders out there, about which we constantly talk when we talk of what has to be or what might have been.

Divers intends much more by a "possible worlds semantics" than merely providing a class of models for a set of axioms and rules of inference in the way mentioned above: he agrees that one can "interpret a modal language extensionally by invoking a model-theoretic approach in which the indices ('worlds') have (intuitively) no modal reference" (Divers 1995, p. 81), and so would agree that he has more in mind than this limited formal task. However, the sense in which providing a "possible worlds semantics" comes to no more than providing traditional Kripke-syle models using indices which are adequate for the job described above does seem to be what most logicians mean by the expression, and I suspect it is what many philosophers of modality mean as well. If so, then Divers's charge is misleadingly stated, since he expects much more from a possible worlds semantics. With this important caveat in mind, let us look at what Divers thinks modal fictionalism cannot deliver and modal realism can.

For Divers, "A possible worlds semantics is a semantic theory which has two components: (i) an interpretation which translates some range of ordinary modal sentences into a medium involving quantification over worlds, and (ii) a theory of validity (typically model-theoretic) that determines formally whether or not arguments formulated in the interpreting medium are valid." (Divers 1995 p. 80) He thinks this "translation" is literally translation, and not just an interpretation for model-theoretic purposes: for the connection between modal sentences and sentences quantifying over possible worlds is meant to be an *analytic* one (p. 80). The other important feature Divers thinks that "possible worlds semantics" has is that the claims about possible worlds are *extensional* claims, which allows the validity of inferences involving them to be determined by the usual methods of "the fully extensional predicate calculus" (p. 81).

Divers is of course allowed to stipulate how he will use his terms as he likes, but insofar as this is intended as an explication of what a possible worlds semantics (in some sense richer than the minimal logican's sense) should be, a point of controversy may be noted. Realists who think that quantification over possible worlds gives insight into the nature of modal truth need not think that such quantificational claims are *analytically*connected with modal claims. They may instead think that possible worlds provide the best theoretical explanation of the truth of modal claims, or are what make those claims true in a way that is to be discovered by synthetic methods. Indeed, in light of the fact that some *prima facie* competent deployers of modal vocabulary (including thoughtful philosophers) do not accept the truth of the possible-worlds "translations" of modal claims that they do accept, we should be reluctant to think that the former are obvious analytic consequences of, let alone synonymous with, the modal claims. Divers cites Graeme Forbes's arguments in Forbes 1985 that we should assume that modal claims and the associated possible worlds claims are synonymous if we are to explain the behaviour of our modal claims by appeal to the possible worlds claims: this is however one side of a controversy between groups that both take themselves to be employing "possible worlds semantics", and employing *worlds* in these semantics, rather than merely employing indicies in formal models of modal languages.

As for the second part of Divers's definition, it is not entirely unambiguous what it is for a claim to be "extensional": there are many ways of drawing the extensional/intensional divide. Divers does not say exactly what he means, but he seems to be using the word in the common sense in which a sentence is extensional if co-referring (or more generally, co-designating) expressions can be substituted *salva*

veritate. Sentences consisting of an "According to PW ..." operator followed by a sub-sentence are thus not extensional, since substituting another sub-sentence (materially) equivalent in truth-value does not always preserve truth. In Divers's example, "There is a world in which there are red dragons" and "1 = 0" will be judged by the fictionalist to have the same truth value, but the expressions "According to PW, there is a world in which there are red dragons" and "According to PW, 1 = 0" will not have the same truth-values (Divers 1985, p. 85). There is another sense in which a claim might be said to be extensional: it is extensional if it does not depend for its truth-value at a world on the truth-value of claims in any other possible world. In this sense, of course, the fictionalist's "According to PW ..." sentences are still not extensional, but neither are the realist's possible worlds "translations" of everyday modal locutions, and possible-worlds "translations" of modal locutions should not in general be thought to be extensional. (One might be tempted more by this view if, for example, one thought that extensionality or intensionality were preserved under meaning equivalence, and accepted that the relevant equivalences were equivalences of meaning, as Divers takes the realist to). There is nothing wrong with Divers's useage, but the ambiguity is possibly confusing. This will become relevant when the question of what advantage extensionality would bring is discussed below.

But let us agree that a "possible worlds semantics" for current purposes has the features Divers ascribes to it. At this point many, realists and fictionalists alike, will already reject the project of attaining a "possible worlds semantics" in Divers's sense (though many would be concerned if they could not have a possible worlds semantics for their favourite formal modal systems, in the more minimal sense). However, let us also grant for the sake of discussion that a possible worlds semantics is desirable, and it would count against a theory if it did not furnish us with one. The next thing that is worth noting is that some possible modal fictionalist theories will straightforwardly provide us with such a semantics. *Broad* modal fictionalists (see main text) take both the talk committed to possible worlds and many modal claims (claims of necessity, and claims about the possible truth of actual falsehoods, etc.) to be true only according to a certain fiction. It is open to such modal fictionalists to accept straightforwardly that the modal sentences were analytically equivalent to their paraphrases in terms of possible worlds. The predicate calculus could then be used to determine validity for modal inferences, and they could have a "possible worlds semantics" for modal claims in as rich a sense as Divers could wish. Divers does not consider this option for modal fictionalists, though his paper is presented as a discussion of Rosen 1990, and Rosen does not mention broad modal fictionalists. Rather, Rosen only considers modal fictionalists who take the modal claims to be equivalent in truth-value to claims about possible worlds prefixed with "according to PW ..." operators. The broad modal fictionalists I have been considering take the equivalence to be between modal claims and *unprefixed* claims about possible worlds, and so arguably fall outside the scope of Divers's discussion. They are worth mentioning even so, since Divers quickly moves from talking about Rosen's particular presentation to a discussion of "modal fictionalism" in general.

Let us then concentrate on the remaining views which come under Divers's attack: those views which take modal statements to be equivalent in truth-value to prefixed claims about possible worlds i.e., claims of the form "According to PW ...". Do these views have to eschew "possible worlds semantics", in Divers's sense? Divers claims that they do, since the analysis in terms of talk about possible worlds provided for modal statements is an analysis in terms of an intensional context, the "according to PW ..."

operator, into which propositions with the same truth-value cannot be substituted *salva veritate*. For those modal fictionalists who do offer this as an analysis, Divers is right that their analysis is not an extensional one. What is not clear is that such fictionalists cannot nevertheless have the advantages associated with extensional semantic treatments of modal language.

Divers says "the distinctive attraction of possible worlds semantic theories is that they combine the virtues of analyticity and extensionality in the treatment of modal languages". Analyticity is presumably held to be a virtue because it is analyticity that provides possible worlds semantic theories "their claim to be the right and genuinely explanatory theories of the semantic features of modal languages", and this is backed in part by an appeal to the arguments of Forbes 1985. Extensionality, the stumbling block for fictionalists according to Divers, is apparently advantageous because (or mainly because) it allows us to determine the validity of "ordinary modal arguments" by "assessing their validity by application of the methods of the fully extensional predicate calculus" (p. 85). Divers also indicates that this advantage is a matter of it being correct according to the theory that "the validity of intuitively valid modal arguments can be demonstrated by first-order methods" (p. 86); he points out, rightly, that merely having this true according to the fiction would not be the same as being able to literally claim it. Divers stresses that it is the combination of these two advantages that is the distinctive benefit fictionalists must forgo (p. 85).

While the modal fictionalists we are now considering do not take ordinary language modal claims to have extensional translations in the language of possible worlds, they may still have a claim to the combined virtue with which Divers is concerned in another, albeit slightly more indirect, way. If they do, then Divers has failed to make his case, since he maintains not only that there is a feature that realist theories have (or perhaps better, can have) that modal fictionalist positions do not (or cannot), but also that the relevant feature is, *prima facie* at least, an advantage. So how may modal fictionalists who take the equivalence in meaning to be one between modal claims and "According to PW ..." claims also take advantage of first-order methods to determine validity for arguments couched in the form of admittedly intensional statements beginning "According to PW ..."?

The most obvious way for a modal fictionalist to attempt to secure this advantage is to insist both that the relevant fictionalist biconditionals are analytic, and that PW is closed under first-order consequence: so that when s follows from r, if "According to PW, r" is true then "According to PW, s" is true, and for any propositions p_1, p_2 ... p_n, when "According to PW, p_1", "According to PW, p_2" ... "According to PW, p_n" are all true, then "According to PW, p_1, p_2, p_3, ... , and p_n" will be true too. Then when one has a collection of premises all suitably prefixed, one will be able to determine whether a conclusion prefixed with "According to PW ..." follows from the premises plus general truths about the modal fiction (such as its closure under first-order consequence) by first-order methods, by seeing whether the proposition embedded in the conclusion follows from the propositions embedded in the premises. This might not quite capture all of the conclusions derivable (conclusions which follow simply from general claims about the fiction will follow in such cases regardless of the specific prefixed premises, for example), but in the ordinary cases when a realist would appeal to the putative analytic equivalences to test the modal arguments for validity, the fictionalist will be able to have recourse to this procedure, which reduces the problem to that of checking statements to see if one is a first-order consequence of the others. The fictionalist’s justification for this will *ex hypothesi* be an appeal to the analytic interderivability of claims

about what is true according to the fiction and modal claims, and so this first-order procedure is available and justifiable in virtue of the analytic connection between the modal claims and the claims involving quantification over possible worlds (albeit that those claims quantify over possible worlds in the scope of "According to PW" operators). True, this advantage will not be because of any extensional features of the "According to PW ..." claims, and so Divers is right in one sense to say that this method is not "extensional". Since the fictionalist who combines analyticity of the relevant equivalences with the above method for securing the use of a first-order decision procedure for validity can have exactly the same advantage that Divers claims for the combination of "the virtues of analyticity and extensionality", Divers's case that there is some *advantage* that realists can claim over fictionalists does not seem to have been made out.

In a later paper (Divers 1999b) Divers sets out to prove a "safety result" which would guarantee the use of extensional reasoning in the scope of an "according to PW" operator for a modal fictionalist. Divers 1999b can thus be seen as a response to Divers's own 1995 challenge, showing how the fictionalist can secure the advantage which Divers 1995 suggests is not available to the modal fictionalist. Not all modal fictionalists would be happy with the resources Divers employs to achieve his result. In particular, Divers employs a primitive necessity operator (p 334), and so his proof as it stands would not be available to an advocate of strong modal fictionalism. (Divers himself notes that the strategy is unavailable to those modal fictionalists who seek a reduction of the modal operators). Fictionalists not concerned to analyse modality, however, may find in Divers 1999b a sufficient answer to Divers 1995.

So to summarise: Divers's claim that "modal fictionalism cannot deliver possible worlds semantics" need not worry modal fictionalists. In the first place, the sense of "possible worlds semantics" Divers employs is not the sense in which many practitioners working with modal logic or the language of possible worlds are most concerned with. Secondly, even given Divers's richer concept of "possible worlds semantics", a conception rich enough that many realists about possible worlds would also not wish to suppose that they should have such a semantics, some modal fictionalists can have such a semantics in exactly Divers's sense (the broad modal fictionalists). Finally, for the remaining modal fictionalists prepared to postulate the appropriate analytic connections, it is possible, at least for all Divers has said, that one might have a semantic treatment of modal claims which treated them as analytically equivalent to claims in the language of possible worlds (albeit prefixed ones) *and* has the virtue of being able to employ first-order methods to determine the validity of many arguments employing premises and conclusions prefixed with "According to PW ..." operators, and so achieve the same advantage Divers claims for analytic, extensional translations. If this is so, then even if there is a sense in which these fictionalists do not have a "possible worlds semantics", they have something just as good, as far as the advantages Divers is concerned with go. Divers 1995 does however provide a challenge for modal fictionalists: if they do want "possible worlds semantics" in Divers's rich sense, they need to provide the details of how it is that they are entitled to the corresponding advantages: perhaps through some analytic equivalence of the sort explored in this note, or perhaps through a system like that of Divers 1999b, or perhaps by some other strategy. (Note that strong modal fictionalists who take their theory to not be descriptive of current usage are unlikely to be tempted by the claim of analytic equivalence and will have to demur from Divers's timid fictionalist proposal, so they at least face an open question if they want the equivalent of a "possible worlds semantics" in Divers's rich sense).

Abstract Objects

It is widely supposed that every object falls into one of two categories: Some things are concrete; the rest abstract. The distinction is supposed to be of fundamental significance for metaphysics and epistemology. The present article surveys a number of recent attempts to say how it should be drawn.

Introduction

The abstract/concrete distinction has a curious status in contemporary philosophy. It is widely agreed that the distinction is of fundamental importance. But there is no standard account of how the distinction is to be explained. There is a great deal of agreement about how to classify certain paradigm cases. Thus it is universally acknowledged that numbers and the other objects of pure mathematics are abstract, whereas rocks and trees and human beings are concrete. Indeed the list of paradigms may be extended indefinitely:

ABSTRACTA	CONCRETA
Classes	Stars
Propositions	Protons

Concepts	The electromagnetic field
The letter A	Stanford University
Dante's *Inferno*	James Joyce's copy of Dante's *Inferno*
...	...

The challenge remains, however, to say what underlies this alleged dichotomy. In the absence of such an account, the philosophical significance of the contrast remains uncertain. We may know how to classify things as abstract or concrete by appeal to "intuition". But unless we know what makes for abstractness and concreteness, we cannot know what (if anything) hangs on the classification.

Historical Remarks

The contemporary distinction between abstract and concrete is not an ancient distinction. Indeed, there is a strong case for the view that despite occasional anticipations, it plays no significant role in philosophy before the 20th century. The modern distinction bears some resemblance to Plato's distinction between Forms and Sensibles. But Plato's Forms were supposed to be causes *par excellence*, whereas abstract objects are normally supposed to be causally inert in every sense. The original "abstract"/"concrete" distinction was a distinction among words or terms. Traditional grammar distinguishes the abstract noun "whiteness" from the concrete noun "white" without implying that this linguistic contrast corresponds to a metaphysical distinction in what they stand for. In the 17th century this grammatical distinction was transposed to the domain of ideas. Locke speaks of the general idea of a triangle which is "neither Oblique nor Rectangle, neither Equilateral, Equicrural nor Scalenon; but all and none of these at once," remarking that even this idea is not among the most "abstract, comprehensive and difficult" (Essay IV.vii.9). Locke's conception of an abstract idea as one that is formed from concrete ideas by the omission of distinguishing detail was immediately rejected by Berkeley and then by Hume. But even for Locke there was no suggestion that the distinction between abstract ideas and concrete or particular ideas corresponds to a distinction among objects. "It is plain, …" Locke writes, "that General and Universal, belong not to the real existence of things; but are Inventions and Creatures of the Understanding, made by it for its own use, and concern only signs, whether Words or Ideas" (III.iii.11).

The abstract/concrete distinction in its modern form is meant to mark a line in the domain of objects. So conceived, the distinction becomes a central focus for philosophical discussion only in the twentieth century. The origins of this development are obscure. But one crucial factor appears to have been the breakdown of the allegedly exhaustive distinction between the mental and the material that had formed the main division for ontologically minded philosophers since Descartes. One signal event in this development is Frege's insistence that the objectivity and a priori of the truths of mathematics entail that numbers are neither material beings nor ideas in the mind. If numbers were material things (or properties of material things), the laws of arithmetic would have the status of empirical generalizations. If numbers were ideas in the mind, then the same difficulty would arise, as would countless others. (Whose mind contains the number 17? Is there one 17 in your mind and another in mine? In that case, the appearance of a common mathematical subject matter is an illusion.) In *The Foundations of Arithmetic* (1884), Frege

concludes that numbers are neither external 'concrete' things nor mental entities of any sort. Later, in his essay "The Thought" (Frege 1918), he claims the same status for the items he calls thoughts -- the senses of declarative sentences -- and also, by implication, for their constituents, the senses of subsentential expressions. Frege does not say that senses are "abstract". He says that they belong to a "third realm" distinct both from the sensible external world and from the internal world of consciousness. Similar claims had been made by Bolzano (1837), and later by Brentano (1874) and his pupils, including Meinong and Husserl. The common theme in these developments is the felt need in semantics and psychology as well as in mathematics for a class of objective (i.e., non-mental) supersensible entities. As this new "realism" was absorbed into English speaking philosophy, the traditional term "abstract" was enlisted to apply to the denizens of this "third realm".

The Way of Negation

Frege's way of drawing the distinction is an instance of what Lewis (1986) calls the **Way of Negation**. Abstract objects are defined as those that lack certain features possessed by paradigmatic concrete things. Nearly every explicit characterization in the literature has this feature. There are, however, several significant difficulties with this approach, at least in its most familiar implementations.

According to Frege's explicit account, the items in the "third realm" are non-mental and non-sensible. But it is unclear what it means to call an object mental or mind-dependent; and to the extent that the notion is intelligible, it is quite unclear whether abstract objects in general satisfy the condition. It is commonly supposed, for example, that the game of chess is an abstract entity (Dummett 1973). But there is certainly a sense in which the game would not have existed were it not for the mental activity of human beings. So at least one sort of mind-dependence would appear to be compatible with abstractness. Moreover, it has sometimes been maintained that the paradigmatic abstract entities -- mathematical objects, universals -- exist only as ideas in the mind of God. The view may be outlandish; but is it a view according to which abstract entities do not exist? Or is it rather a view according to which certain abstract entities are also mind-dependent? Insofar as the latter interpretation is not straightforwardly contradictory, the definition of "abstract" should not require mind-independence.

Perhaps more importantly, Frege's identification of the abstract with the realm of non-sensible non-mental things entails that unobservable physical objects such as quarks and electrons should be classified as abstract entities. But this is at odds with standard usage, and almost certainly with Frege's intention.

The Non-Spatiality Criterion

Contemporary purveyors of the Way of Negation standardly amend Frege's criterion by requiring that abstract objects be **non-spatial** or **causally inefficacious** or both. Indeed, if any characterization of the abstract deserves to be regarded as the standard one, it is this: An abstract entity is a non-spatial (or non-spatiotemporal) causally inert thing. But this standard characterization presents a number of perplexities.

Consider the requirement that abstract objects be non-spatial or non-spatiotemporal. Some of the paradigms of abstractness are non-spatiotemporal in a straightforward sense. It makes no sense to ask where the cosine function is. Or if it does make sense to ask, the only sensible answer is that it is nowhere. Similarly, it makes little sense to ask when the Pythagorean theorem came to exist. And if it does make sense to ask, the only sensible answer is that it has always existed, or perhaps, that it does not exist 'in time' at all. These paradigmatic abstracta have no non-trivial spatial or temporal properties. They have no spatial location, and they exist nowhere in particular in time. But consider the game of chess. Some philosophers take the view that chess is like a mathematical object in these respects. But that is certainly not the most natural view. The natural view is that chess was invented at a certain place and time (though it may be hard to say exactly where or when); that before it was invented it did not exist at all; that it was imported from India into Persia in the 7th century; that it has changed in various respects over the years, and so on. The only reason to resist this natural description would appear to be the thought that since chess is clearly an abstract object (it's not a physical object, after all!), and since abstract objects do not exist in spacetime (by definition!), chess must resemble the cosine function in its relation to space and time. However, one might with equal justice regard the case of chess and other "artificial" abstract entities as a counterexample to the view that abstract objects in general possess only trivial spatial and temporal properties.

This is not necessarily ground for abandoning the non-spatiotemporality criterion. Even if there is a sense in which some abstract entities possess non-trivial spatiotemporal properties, it might still be said thought that concrete entities 'exist in spacetime' *in a distinctive way*, and that abstract entities may be characterized as items that fail to exist in space and time in the manner characteristic of concrete objects.

The paradigmatic concrete objects generally occupy a relatively determinate spatial volume at each time at which they exist, or a determinate volume of spacetime over the course of their existence. It makes sense to ask of any such object, "Where is it now and how much space does it occupy?", even if the answer must in some cases be somewhat vague. By contrast, even if the game of chess is somehow "implicated" in space and time, it makes no sense to ask how much space it now occupies -- or if it does make sense to ask, the only sensible answer is that it occupies no space at all (which is not to say that it occupies a spatial point.) And so it might be said: An object is abstract if it fails to occupy anything like a determinate region of space (or spacetime).

This promising suggestion faces two sorts of difficulty. First, according to some interpretations of quantum mechanics, microscopic physical objects fail to occupy anything like a determinate region of space. If we consider an isolated proton whose position has not been measured for some time, the question "Where is it now and how much space does it occupy?" will have no straightforward answer. And yet no one would suggest that an unobserved proton is an abstract entity. Second, it is not out of the question that certain items that are standardly regarded as abstract may nonetheless occupy determinate volumes of space and time. It is generally agreed that sets and functions are abstract entities. So consider the various sets composed from Peter and Paul: {Peter, Paul}, {{Peter}, {Peter, Paul}}, etc. The question, "Where are these things and how much space do they occupy?" does not arise in the normal course of inquiry. Moreover, many philosophers will be inclined to say that either the question makes no sense, or the answer is a simple "Nowhere. None." But this would appear to be another unreflective

application of the unpersuasive inference noted above. In this case: Sets are abstract; abstract objects do not exist in space. So sets must not exist in space. But as before, there is reason to doubt the cogency of such an inference. Let it be granted that pure sets are like the cosine function: located nowhere in space a nd nowhere in particular in time. Is there a principled objection to the view that impure sets exist where and when their members do? It is not unnatural to say that a set of books is located on a certain shelf in the library. So why not say that the sets containing Peter and Paul exist wherever and whenever Peter and Paul themselves exist, and that in general an impure set exists where and when its spatiotemporally located ur-elements are located? To be sure, nothing in set theory forces us to say this. But the applications of set theory to the concrete domain are not inconsistent with this manner of speaking. So, while it may be clear that the impure sets are abstract and not concrete, it is quite unclear whether they fail to exist in space in much the same sense in which paradigmatic concreta exist in space. This suggests that it may have been a mistake from the start to suppose that the distinction between concrete and abstract is at bottom a matter of spatiotemporal locatedness.

The Causal Inefficacy Criterion

The most widely accepted version of the Way of Negation has it that abstract objects are distinguished by their causal inefficacy. Concrete objects (whether mental or physical) have causal powers; numbers a nd functions and the rest make nothing happen. There is no such thing as causal commerce with the game of chess. And even if impure sets do in some sense exist in space, it is easy enough to believe that they make no distinctive causal contribution to what transpires. Peter and Paul may have effects individually; and they may have effects together which neither has on his own. But these joint effects are naturally construed as effects of two concrete objects acting jointly, or perhaps as effects of their mereological aggregate (itself a paradigm concretum), rather than as effects of some set-theoretic construction. (Suppose Peter and Paul together tip a balance. If we entertain the possibility that this event is caused by a set, we shall have to ask which set caused it: the set containing just Peter and Paul? Some more elaborate construction based on them? Or perhaps the set containing the molecules that compose Peter and Paul? This proliferation of possible answers suggests that it was a mistake to credit causal powers to sets in the first place.)

There are no decisive intuitive counterexamples to this account of the abstract/concrete distinction. The chief difficulty is rather conceptual. The causal relation, strictly speaking, is a relation among events. If we say that the rock caused the window to break, what we mean is that some event involving the rock caused the breaking. If the rock itself is a cause, it is a cause in some derivative sense. But this derivative sense has proved elusive. The rock's hitting the window is an event in which the rock "participates" in a certain way, and it is because the rock participates in events in this way that we credit the rock itself with causal efficacy. But what is it for an object to participate in an event? Suppose John is thinking about the Pythagorean Theorem and you ask him to say what's on his mind. His response is an event: the utterance of a sentence; and one of its causes is the event of John's thinking about the theorem. Does the Pythagorean Theorem "participate" in this event? There is surely *some* sense in which it does. The event consists in John's coming to stand in a certain relation to the theorem, just as the rock's hitting the window consists in the rock's coming to stand in a certain relation to the window. But we do not credit

the Pythagorean Theorem with causal efficacy simply because it participates in this sense in an event which is a cause. The challenge is therefore to characterize the distinctive manner of "participation in the causal order" which distinguishes the concrete entities. This problem has received relatively little attention. There is no reason to believe that it cannot be solved. But in the absence of a solution, this standard version of the Way of Negation must be reckoned unsatisfactory.

The Way of Example

In addition to the Way of Negation, Lewis identifies three main strategies for explaining the abstract/concrete distinction. According to the **Way of Example**, it suffices to list paradigm cases of abstract and concrete entities in the hope that the sense of the distinction will somehow emerge. If the distinction were primitive and unanalyzable, this might be the only way to explain it. But as we have remarked, this approach is bound to call the interest of the distinction into question. The abstract/concrete distinction matters because abstract objects as a class appear to present certain general problems in epistemology and the philosophy of language. It is supposed to be unclear how we come by our knowledge of abstract objects in a sense in which it is not unclear how we come by our knowledge of concrete objects (Benacerraf 1973). It is supposed to by unclear how we manage to refer determinately t o abstract entities in a sense in which it is not unclear how we manage to refer determinately to other things (Benacerraf 1973, Hodes 1984). But if these are genuine problems, there must be some account of why abstract objects as such should be especially problematic in these ways. It is hard to believe that it is simply their primitive abstractness that makes the difference. It is much easier to believe that it is their non-spatiality or their causal inefficacy or something of the sort. It is not out of the question that the abstract/concrete distinction is fundamental, and that the Way of Example is the best we can do by way of elucidation. But if so, it is quite unclear why the distinction should make a difference.

The Way of Conflation

According to the **Way of Conflation**, the abstract/concrete distinction is to be identified with one or another metaphysical distinction already familiar under another name: as it might be, the distinction between sets and individuals, or the distinction between universals and particulars. There is no doubt that some authors have used the terms in this way. But this sort of conflation is relatively rare nowadays. As most philosophers use the term, a claim to the effect that sets (or universals) are the only abstract objects would amount to a substantive metaphysical thesis in need of substantive defense.

The Way of Abstraction

The most important alternative to the Way of Negation is what Lewis calls the **Way of Abstraction**. According to a longstanding tradition in philosophical psychology, abstraction is a distinctive mental process in which new ideas or conceptions are formed by considering several objects or ideas and omitting the features that distinguish them. One is given a range of white things of varying shapes and

sizes; one ignores or "abstracts from" the respects in which they differ, and thereby attains the abstract idea of whiteness. Nothing in this tradition requires that ideas formed in this way represent or correspond to a distinctive class of objects. But it might be maintained that the distinction between abstract and concrete objects should be explained by reference to the psychological process of abstract ion or something like it. The simplest version of this strategy would be to say that an object is abstract if it is (or might be) the referent of an abstract idea, i.e., an idea formed by abstraction.

So conceived, the Way of Abstraction is wedded to an outmoded philosophy of mind. But a related approach has gained considerable currency in recent years. Crispin Wright (1983) and Bob Hale (1987) have developed an account of abstract objects that takes leave from certain suggestive remarks in Frege (1884). Frege notes (in effect) that many of the singular terms that refer to abstract entities are formed by means of functional expressions. We speak of *the shape of* an object, *the direction of* a line, *the number of* books. Of course many singular terms formed by means of functional expressions denote ordinary concrete objects: "the father of Plato", "the capital of France". But the functional terms that pick out abstract entities are distinctive in the following respect: W here '$f(a)$' is such an expression, there is typically an equation of the form

$$f(a) = f(b) \text{ if and only if } a\ R\ b,$$

where R is an equivalence relation. (An equivalence relation is a relation that is reflexive, symmetric and transitive.) For example,

> The direction of *a* = the direction of *b* iff *a* is parallel to *b*.
>
> The number of *F*s = the number of *G*s iff there are just as many *F*s as *G*s.

Moreover, these equations (or abstraction principles, as they are sometimes called) appear to have a special semantic status. While they are not strictly speaking definitions of the functional expression that occurs on the left, they would appear to hold in virtue of the meaning of that expression. To understand the term "direction" is (in part) to know that "the direction of a" and "the direction of b" refer to the same entity if and only if the lines a and b are parallel. Moreover, the equivalence relation that appears on the right hand side of the equation would appear to be semantically and perhaps epistemologically prior to the functional expression on the left (Noonan 1978). Mastery of the concept of a direction presupposes mastery of the concept of parallelism, but not vice versa.

The availability of abstraction principles meeting these conditions may be exploited in several ways to yield an account of the distinction between abstract and concrete objects. When 'f' is a functional expression governed by an abstraction principle, there will be a corresponding concept $\boldsymbol{K}f$ such that X is $\boldsymbol{K}f$ iff for some y, $x = f(y)$. The simplest version of this approach to the Way of Abstraction is then to say that X is an abstract object if (and only if?) X is an instance of some kind $\boldsymbol{K}f$ whose associated functional expression 'f' is governed by a suitable abstraction principle. m

This simple account is liable to a number of objections.

- As we have noted, pure sets are paradigmatic abstract objects. But it is not clear that they satisfy the proposed criterion. According to naïve set theory, the functional expression ‘set of’ is indeed characterized by a putative abstraction principle.

  The set of *F*s = the set of *G*s iff for all *x*, *x* is *F* iff *x* is *G*.

  But this principle is inconsistent, and so fails to characterize an interesting concept. In contemporary mathematics, the concept of a set is not normally introduced by abstraction. It remains an open question whether something like the mathematical concept of a set can be characterized by a suitably restricted version of the naïve abstraction principle. But even if such a principle is available, it is unlikely that the epistemological priority condition will be satisfied. (That is, it is unlikely that mastery of the concept of set will presuppose mastery of the equivalence relation that figures on the right hand side.) It is therefore uncertain whether the Way of Abstraction so understood will classify the objects of pure mathematics as abstract entities (as it presumably must).
- As Dummett (1973) has noted, in many cases the standard names for paradigmatically abstract objects do not assume the functional form to which the definition adverts. Chess is an abstract entity. But we do not understand the word "chess" as a synonymous with an expression of the form "*f*(*x*)" where "*f*" is governed by an abstraction principle. Similar remarks would seem to apply to such things as the English language, social justice, architecture, Audrey Hepburn's smile. (In this last case, we are to imagine that Hepburn's smile is essentially connected to its bearer. Someone else might smile just like Hepburn, but her smile would not be *Hepburn's* smile.) If so, the Fregean approach undergenerates: At best it may be said to characterize a special case of the general concept of an abstract entity.
- As formulated, the account would appear to admit of counterexamples. A mereological fusion of concrete objects is itself a concrete object. But the concept of a mereological fusion is governed by a principle with all the marks of an abstraction principle:

  The fusion of the *F*s = the fusion of the *G*s iff the *F*s and *G*s cover one another.
  (The *F*s cover the *G*s iff every part of every *G* has a part in common with an *F*.)

  Or consider: A train is a maximal string of railroad carriages, all of which are connected to one another. We may define a functional expression, ‘the train of *x*’, by means of an "abstraction" principle:

  The train of *x* = the train of *y* iff *x* and *y* are carriages and *x* and *y* are connected.

  We may then say that *x*is a train iff for some carriage *y*, *x*is the train of *y*. The simple account thus yields the consequence that trains are to be reckoned abstract entities.

It is unclear whether these objections apply to the more sophisticated abstractionist proposals of Wright and Hale. This Fregean approach to the abstract/concrete distinction is clearly promising. But like most other approaches to explaining the distinction, it has not yet assumed its final form. Definitive assessment would therefore be premature.

Further Reading

Zalta (1983) is an axiomatic theory of abstract objects. Putnam (1975) makes the case for abstract objects on scientific grounds. Field (1980) and (1989) make the case against abstract objects. Bealer (1993) and Tennant (1997) present a priori arguments for the necessary existence of abstract entities. The dispute over the existence of abstracta is reviewed in Burgess and Rosen (1997).

Frege's Logic, Theorem, and Foundations for Arithmetic

Frege formulated two distinguished formal systems and used these systems in his attempt both to express certain basic concepts of mathematics precisely and to derive certain mathematical laws from the laws of logic. In his *Begriffsschrift* of 1879, he developed a second-order predicate calculus and used it both to define interesting mathematical concepts and to state and prove mathematically interesting propositions. However, in his *Grundgesetze der Arithmetik* of 1893/1903, Frege added (as an axiom) what he thought was a distinguished logical proposition (Basic Law V) and tried to derive the fundamental theorems of various mathematical (number) systems from this proposition. Unfortunately, not only did Basic Law V fail to be a logical proposition, but the resulting system proved to be inconsistent, for it was subject to Russell's Paradox.

Although the inconsistency in Frege's *Grundgesetze* is widely known, it is not very well known that a deep theoretical accomplishment can be extracted from his work. The *Grundgesetze* contains all the essential steps of a valid proof (in second-order logic) of the fundamental propositions of arithmetic from a single consistent principle. This consistent principle, known in the literature as "Hume's Principle", asserts that for any concepts *F* and *G*, the number of *F*-things is equal to the number *G*-things if and only if there is a one-to-one correspondence between the *F*-things and the *G*-things. In the *Grundgesetze*, Frege used Basic Law V to derive Hume's Principle, but the derivations of the fundamental propositions of arithmetic from Hume's Principle do not essentially require Basic Law V. So by setting aside the derivation of Hume's Principle from the inconsistent Basic Law V and focusing on Frege's proofs of the basic propositions of arithmetic, his theoretical accomplishment emerges much more clearly, for his work shows us how to prove the Dedekind/Peano axioms for number theory from Hume's Principle in second-order logic. This achievement, which involves some remarkably subtle chains of definitions and logical reasoning, has become known as Frege's Theorem. [See Boolos (1990), p. 268.]

The principal goals of this essay are: (1) to review in some detail the essential features of Frege's logical systems, (2) to work through the derivations involved in Frege's Theorem, and (3) to frame the most important philosophical questions that arise in connection with this theorem. In addition, we hope to prepare students of Frege to read his original work (in translation) and to prepare the reader to understand a number of excellent articles in the secondary literature on Frege's work.

To accomplish these goals, we presuppose only a familiarity with the first-order predicate calculus. We show how to extend this language and logic to include the most salient features of Frege's second-order

predicate calculus, his theory of concepts, and his theory of extensions. Our discussion will be largely based upon material drawn from Frege's three principal published works:

- *Begriffsschrift, eine der arithmetischen nachgebildete Formelsprache des reinen Denkens* (‘Concept Notation: A formula language of pure thought, modelled upon that of arithmetic’), 1879
- *Die Grundlagen der Arithmetik* (‘The Foundations of Arithmetic’), 1884
- *Grundgesetze der Arithmetik* (‘Basic Laws of Arithmetic’), 1893/1903

We will refer to these works with boldfaced abbreviations of their German titles: **Begr**, **Gl** and **Gg**, respectively. Those readers already familiar with parts of Frege's texts may wish to skip the discussion of that material.

---

§1: Frege's Predicate Calculus and Theory of Concepts

In this section, we describe the language and logic of Frege's predicate calculus. We explain his function-argument analysis of atomic sentences and his definition of concepts in terms of functions, give examples of his ‘concept script’, and discuss the Rule of Substitution in his logic. We also show how Frege's Rule of Substitution corresponds to a comprehension principle for concepts in second-order logic, and we introduce and explain λ-notation to help us distinguish open formulas and complex names of concepts. Readers who are already familiar with these ideas may wish to skip ahead to Section 2.

The Language

In **Begr**, Frege invented the predicate calculus. It will soon become clear that the language and logic of his predicate calculus are ‘second-order’. The language included not only the variables *x*,*y*,*z*, ... , which

range over *objects*, but also included the variables *f*,*g*,*h*, ... , which range over *functions*. Frege rigidly distinguished objects from functions and so we may think of these variables as ranging over separate, mutually exclusive domains. Frege took functional application ‘*f*(*x*)’ as the principal operation for forming complex names of objects in his language. The expression ‘*f*(*x*)’ denotes the object to which the function *f* maps the object *x*. Frege called the object *x* the ‘argument’ of the function *f* and called *f*(*x*) the ‘value’ of the function. Since Frege also recognized two special objects he called *truth-values* (The True and The False), he defined a *concept* to be any function that always maps its arguments to truth-values. For example, whereas ‘x^2 +3’ and ‘father-of(*x*)’ denote ordinary functions, the expressions ‘Happy(*x*)’ and ‘*x* > 5’ denote concepts. The former denotes a concept which maps any object that is happy to The True and all other objects to The False; the latter denotes a concept that maps any object that is greater than 5 to The True and all other objects to The False. Given that concepts like *being happy* and *being greater than* 5 map their arguments to truth values, the atomic sentences of Frege's language, such as ‘Happy(*b*)’ and ‘*4* > 5’, become *names* of truth-values.

In what follows, we use the symbols *F*,*G*, ... as variables ranging over concepts and we often write ‘*Fx*’ (instead of ‘*F*(*x*)’) to express the claim that concept *F* maps *x* to The True. When this claim is true, Frege would say that *x falls under* the concept *F*.

When *f* is a function of two arguments *x* and *y* and *f* always maps its pair of arguments to a truth value, Frege would say that *f* is a relation. We shall use the expression ‘*Rxy*’ (or sometimes ‘*R*(*x*,*y*)’) to assert that the relation *R* maps *x* and *y* (in that order) to The True. In what follows, we shall sometimes write the symbol that denotes a mathematical relation in the usual ‘infix’ notation; for example, ‘>’ denotes the greater-than relation in the expression ‘*x* > *y*’.

Now that we have explained Frege's analysis of the atomic statements ‘*Fx*’ and ‘*Rxy*’ familiar to modern students of logic, we turn next to the more complex statements of his language. Frege developed his own graphical notation for asserting complex statements involving negations, conditionals, and universal quantification. If we ignore the fact that Frege used Gothic letters as variables of quantification, certain letters as bound variables in names of courses-of-values, and certain other letters as placeholders in the names of functions, then Frege's notation for the logical notions ‘not’, ‘if-then’, ‘every’ and ‘some’ can be described in the following table:

Logical Notion	**Modern Notation**	**Frege-Style Notation**
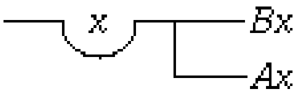
It is not the case that *Fx*	$\neg Fx$	If *Fx* then *Gy*	$Fx \rightarrow Gy$	Every *x* is such that *Fx*	$\forall xFx$	Some *x* is such that *Fx*	$\neg\forall x\neg Fx$, i.e., $\exists xFx$	
Every *F* is such that *Fa*	$\forall F\, Fa$	
Some F is such that Fa	$\neg\forall F \neg Fa$, i.e., $\exists F\ Fa$	
So, for example, whereas a modern logician would symbolize the claim ‘All *A*s are *B*s’ as:

$\forall x(Ax \rightarrow Bx)$

Frege would symbolize this claim as follows:



However, since Frege's notation was never adopted as a standard, we shall instead use the more familiar modern notation in the remainder of this essay. [See Beaney (1997, Appendix 2) and Furth (1967) for more detailed introduction to Frege's notation.] We shall assume that the reader is familiar with the fact that negations (‘$\neg\varphi$’) and conditionals (‘$\varphi \rightarrow \psi$’) can be used to define the other molecular formulas such as conjunctions (‘φ & ψ’), disjunctions (‘φ v ψ’), and biconditionals (‘$\varphi \equiv \psi$’). Moreover, it is important to mention that Frege took identity statements of the form ‘$x = y$’ as primitive in his language. Whereas ‘$2^2 = 4$’ names The True, ‘$2^2 = 3$’ names The False. The statement form ‘$f(x) = y$’ plays an important role in Frege's axioms and definitions. Note finally that since Frege allowed quantification over both objects and functions, the language of his predicate calculus becomes ‘second-order’.

The Logic

Frege's logic consisted of basic axioms and rules of inference that governed the permissible inferences within his system. His axioms included familiar axioms of propositional logic, second-order predicate logic, and the logic of identity. For example, where φ and ψ are any formulas and ‘*a*’ is any object term and ‘*P*’ is any concept term, then the following were among the basic laws of Frege's system:

- $\varphi \rightarrow (\psi \rightarrow \varphi)$
- $(\forall x Px) \rightarrow Pa$
- $(\forall F\ Fa) \rightarrow Pa$
- $a = b \rightarrow \forall F(Fa \equiv Fb)$

[Frege's most well-known codification of these laws occurs in **Gg I**, §47; however, the above laws are first introduced in **Gg I**, §§18, 20, 25, and 20, respectively.] We shall simplify our discussion in what follows by assuming that the usual axioms of the modern second-order predicate calculus apply to Frege's system. These are essentially the same as the axioms for the first-order predicate calculus, except for the addition of laws for the second-order quantifiers $\forall F$ and $\exists F$ which correspond to the laws governing the first-order quantifiers $\forall x$ and $\exists x$.

Although these axioms of Frege's logic are familiar to us, the rules of inference in Frege's system are not as familiar. The reason is that the rules govern not only his graphical notation for molecular and quantified formulas, but also his special purpose symbols, such as certain lowercase letters used as placeholders, certain Gothic and letters used as bound variables, and various other signs of his system we have not yet mentioned. Since these will play no role in the discussion that follows, we shall again simplify our discussion by assuming that the usual rules of the modern second-order predicate calculus apply to Frege's system. Again, these are essentially the same as the rules for the first-order predicate calculus, except for the addition of new rules for the second-order quantifiers that correspond to the generalization and instantiation rules (i.e., introduction and elimination rules) for the first-order quantifiers.

The Rule of Substitution

There is, however, one distinguished rule of Frege's system that will play an important role in what follows, namely, his Rule of Substitution. For the purposes of this discussion, we may formulate the rule in the following somewhat simplified manner:

> **Rule of Substitution** (Simplified Version):
> In any statement of the form ...*Fx*... (in which the variable *F* is free) which is derivable as a theorem of logic, we may substitute any open formula $\varphi(x)$ (with the free variable *x*) for all the occurrences of the atomic formula *Fx* in ...*Fx*... .

To see this rule in action, first consider the following theorem of (Frege's) second-order predicate logic:

(A) $\forall x(Fx \equiv Fx)$.

Now Frege's Rule of Substitution not only allows us to substitute the atomic formula '*Ox*' (which might represent the claim '*x is odd*') for the formula *Fx* to derive the true statement $\forall x(Ox \equiv Ox)$, but also allows us to substitute complex formulas with a free variable *x* for '*Fx*'. So, for example, we are allowed substitute the formula '*Ox* & *x* > 5' ('*x* is odd and *x* is greater than 5') for '*Fx*' in (A) to derive the following from (A):

(B) $\forall x(Ox \,\&\, x > 5 \equiv Ox \,\&\, x > 5)$

Inferences such as this will be valid no matter what complex formula with *x* free we substitute for *Fx* in our universal claim (A). This is what justifies Frege's Rule of Substitution.

In what follows, we will assume that the Rule of Substitution can be generalized to relations, so that we can uniformly replace the formula *Rxy* (in a theorem of logic with *R* free) by a complex formula $\varphi(x,y)$ (in which both *x* and *y* are free).

The Theory of Concepts

The Rule of Substitution has rather powerful consequences. It implies that there exists a concept corresponding to every open formula with a free variable *x*. To see that this is a consequence of the rule, note that it follows from (A) by existential generalization that:

$$\exists G \forall x(Gx \equiv Fx)$$

Frege's Rule of Substitution now allows us to substitute any formula with free variable *x* for *Fx*. In other words, every instance of the following Comprehension Principle for Concepts is derivable in Frege's system:

> **Comprehension Principle for Concepts**:
> $\exists G \forall x(Gx \equiv \varphi(x))$,
> where $\varphi(x)$ is any formula which has *x* free and which has no free *G*s.

Similarly, from the theorem of logic:

$$\forall x \forall y(Rxy \equiv Rxy)$$

one can generalize and then use the Rule of Substitution to derive the following Comprehension Principle for Relations:

> **Comprehension Principle for Relations**:
> $\exists R \forall x \forall y(Rxy \equiv \varphi(x,y))$,
> where $\varphi(x,y)$ is any formula with *x* and *y* free and which has no free *R*s.

Although Frege didn't explicitly formulate these Comprehension Principles, they constitute a very important generalization about his system that reveals its underlying theory of concepts and relations. We can see these principles at work if we return to the example used above. The following is an instance of the Comprehension Principle for Concepts and so constitutes a theorem of Frege's system:

$$\exists G \forall x(Gx \equiv Ox \ \& \ x > 5)$$

This asserts: there exists a concept *G* such that for every object *x*, *x* falls under *G* if and only if *x* is odd and greater than 5. We can see, therefore, that Frege's Rule of Substitution essentially treats an open formula like ‘*Ox* & *x* > 5’ as if it were a name of a complex concept. Similarly, the following is an instance of the Comprehension Principle for Relations:

$$\exists R \forall x \forall y(Rxy \equiv Ox \ \& \ x > y)$$

This asserts the existence of a relation that objects x and y bear to one another just in case the complex condition Ox & $x > y$ holds.

Logicians nowadays typically distinguish the open formula $\varphi(x)$ from the corresponding name of a concept. They use the notation $[\lambda x\ Ox\ \&\ x > 5]$ as the name of the concept *being an object x such that x is odd and x is greater than* 5 (or, more naturally, ‘being odd and greater than 5’). The term-forming operator ‘λx’ (‘being an x such that’) combines with a formula $\varphi(x)$ in which x is free to produce $[\lambda x\ \varphi(x)]$. The λ-expression is a name of the concept expressed by the formula. This notation can be extended for relational concepts. The expression:

$$[\lambda xy\ Ox\ \&\ x > y]$$

names the 2-place relation *being an x and y such that x is odd and greater than y*. So we will use expressions of the more general form $[\lambda xy\ \varphi(x,y)]$ in what follows. The reader should note, however, that insofar as λ-expressions are taken to be predicates, Frege would not have accepted the idea that these are complete expressions that name concepts. But we shall not discuss Frege's reasons for this in the present essay.

This λ-notation is governed by the following simple logical principle known as λ-Conversion. Let $\varphi(x)$ be any formula in which the variable x is free, and let $\varphi(y/x)$ be the result of substituting the variable y for x everywhere in $\varphi(x)$. Then the principle of λ-Conversion is:

λ-Conversion:
$$\forall y([\lambda x\ \varphi(x)]y \equiv \varphi(y/x))$$

This asserts that an object y falls under the concept $[\lambda x\ \varphi(x)]$ if and only if $\varphi(y/x)$ holds. So, using our example, the following is an instance of λ-conversion:

$$\forall y([\lambda x\ Ox\ \&\ x > 5]y \equiv Oy\ \&\ y > 5)$$

This asserts that an object y falls under the concept *being odd and greater than* 5 if and only if y is odd and greater than 5. Note that when the variable y is instantiated to some object term, the resulting instance of λ-Conversion is a biconditional. Some logicians call the rule of inference derived from the right-to-left direction of such biconditionals ‘λ-Abstraction’. For example, the inference from

$$O6\ \ \&\ \ 6 > 5$$

to

$$[\lambda x\ Ox\ \&\ x > 5]6$$

is justified by λ-Abstraction.

The principle of λ-Conversion can be generalized, so that it covers relations as well:

$$\forall z \forall w([\lambda xy\ \varphi(x,y)]zw \equiv \varphi(z/x, w/y))$$

The reader should construct an instance of this principle using our example [λ*xy Ox* & *x* > y].

To reiterate, then, Frege's Rule of Substitution allows us to instantiate $\varphi(x)$ for the free variable *F* in theorems of logic as if $\varphi(x)$ were a λ-expression and constituted a name of a concept. In what follows, we shall make use of this λ-notation. Indeed, λ-notation is required if we are to give a more precise formulation of the Rule of Substitution; the precise formulation of the rule for concepts is:

> **Rule of Substitution**:
> The λ-expression $[\lambda x\ \varphi(x)]$ may be uniformly substituted for the occurrences of the variable *F* in any theorem of logic containing *F* free.

(The formulation for relations is similar.) Moreover, the principle of λ-Conversion simplifies the strict proof of the equivalence of Frege's Rule of Substitution and the Comprehension Principle for Concepts. As it turns out, not only does Frege's Rule of Substitution imply the Comprehension Principle for Concepts, but the converse also holds: the Comprehension Principle for Concepts implies the Rule of Substitution. [For a proof sketch, see Boolos (1985) p. 161-162. Note that instead of $[\lambda x\ \varphi(x)]$, Boolos uses the notation {*a*: *Aa*}; elsewhere, in (1987) for example, Boolos uses the notation [*x* : *A*(*x*)] to denote concepts.]

It is important to appreciate that the system we have just described, i.e., Frege's system of second order logic and the theory of (relational) concepts that he developed in **Begr**, is consistent. (It is only later in **Gg**, when Frege added Basic Law V to this consistent basis, that the resulting system became inconsistent.) Its underlying comprehension principle for concepts ensures that the domain of concepts is very rich. Each concept has a negation, every pair of concepts has a conjunction, every pair of concepts has a disjunction, etc. The reader should be able to write down instances of the comprehension principle which demonstrate these claims. In Part III of **Begr**, Frege applied his system to the ‘theory of sequences’ (we call these ‘*R*-series’ below). It is here that Frege presents his celebrated definition of the ‘ancestral’ of a relation and first proves the generalized analogues of the principle of mathematical induction, as well as various structural properties of the ancestral. We shall postpone further discussion of this work until §§4 and 5, where we reproduce Frege's definition of the ancestral of a relation and show how Frege incorporated this definition into the proof of mathematical induction, respectively.

§2: Frege's Theory of Extensions: Basic Law V

[Note: This section is included to give an historical understanding of Frege's system. It is not required for

understanding the proof of Frege's Theorem.]

The principle that undermined Frege's system (Basic Law V) was one that attempted to systematize the notions ‘course-of-values of a function’ and ‘extension of a concept’. The course-of-values of a function f is something like a set of ordered pairs that records the value $f(x)$ for every argument x. For example, the course-of-values of the function *father of x* records, among other things, that Bill Clinton is the value of the function when Chelsea Clinton is the argument. The course-of-values for the function x^2 records, among other things, that the number 4 is the value when the number 2 is the argument, that 9 is the value when 3 is the argument, etc. The extension of a concept is something like the set of all objects that fall under the concept. For example, the extension of the concept *x is a positive even integer less than 8* is something like the set consisting of the numbers 2, 4,and 6 (strictly speaking, the extension of this concept records The True as the value when 2, 4 and 6 are supplied as argument, and records that The False is the value when anything else is supplied as argument). Since concepts are just functions from objects to truth values, the extension of a concept is simply the course-of-values which records which objects that concept maps to The True.

Notation for Courses-of-Values

Frege introduces notation for courses-of-values in **Gg I**, §9. He switched to the lower case letters ε and α when writing the names of courses-of-values and extensions. He used something like the notation $\acute{\varepsilon} f(\varepsilon)$ to designate the course-of-values of the function f. In the special case where f is the concept F, he used the notation $\acute{\varepsilon} F\varepsilon$ to designate the extension of the concept F.

Here are two pairs of examples of Frege's notation---the first are examples of courses-of-values and the second are examples of extensions. The first pair of examples comes from **Gg I**, §9. Frege uses the notation:

$$\acute{\varepsilon}(\varepsilon^2 - \varepsilon)$$

to denote the course-of-values of the function:

$$x^2 - x$$

He also uses:

$$\acute{\alpha}(\alpha \cdot (\alpha - 1))$$

to denote the course-of-values of the function:

$$x \cdot (x - 1)$$

Frege then notes that:

$$\forall x[x^2 - x = x \cdot (x - 1)]$$

always has the same truth value as the following:

$$\grave{\varepsilon}(\varepsilon^2 - \varepsilon) = \grave{\alpha}(\alpha \cdot (\alpha - 1))$$

This equivalence will become embodied in Basic Law V.

Here is a second example, this time involving a pair of concepts. Consider the concept *that which when added to* 4 *equals* 5, or using λ-notation, the following concept:

$$[\lambda x\, x + 4 = 5]$$

Frege would use the following notation to denote the extension of this concept:

$$\grave{\varepsilon}(\varepsilon + 4 = 5)$$

Now consider the concept *that which when added to* 2^2 *equals* 5 (i.e., $[\lambda x\, x + 2^2 = 5]$). Frege would use the following notation to denote the extension of this concept:

$$\grave{\alpha}(\alpha + 2^2 = 5)$$

Note that it seems natural to identify these two extensions whenever all and only the objects that fall under the first concept fall under the second.

From these examples, it should be clear that when $\varphi(x)$ is any formula in which the variable x is free, we may write $\grave{\varepsilon}(\varphi(\varepsilon/x))$ to designate the extension of the concept $[\lambda x\, \varphi(x)]$. Those readers already familiar with the 'λ-calculus' should remember that $\grave{\varepsilon}(\varphi(\varepsilon))$ denotes an object, that $[\lambda x\, \varphi(x)]$ denotes a concept, and that Frege rigorously distinguished objects and concepts and supposed them to constitute mutually exclusive domains. One subtlety that we have ignored in the examples of the previous paragraph is the difference between Frege's notation

$$\grave{\varepsilon}(\varepsilon + 4 = 5)$$

and our notation:

$$\grave{\varepsilon}([\lambda x\, x + 4 = 5]\varepsilon)$$

However, Frege's notation is equivalent to this latter notation, given that λ-Conversion allows us to convert

$$[\lambda x\; x + 4 = 5]\varepsilon$$

to:

$$\varepsilon + 4 = 5$$

In general, whenever we have a complex formula $\varphi(x)$ in which the variable x is free, and $\varphi(\varepsilon/x)$ is the result of replacing ε for x everywhere in $\varphi(x)$, we may always rewrite:

$$\grave{\varepsilon}([\lambda x\; \varphi(x)]\varepsilon)$$

as:

$$\grave{\varepsilon}(\varphi(\varepsilon/x))$$

Frege doesn't require this ‘Rewrite Rule’, since he doesn't use λ-notation. But since it is logically more perspicuous to distinguish open formulas from the corresponding names of concepts, it is important to make this rule explicit.

Membership in an Extension

If we remember that the extension of a concept is something like the set of objects that fall under the concept, then we could replace Frege's talk of ‘extensions’ by talk of ‘sets’ and use the following ‘set notation’ to refer to the set of objects that when added to 4 yield 5 and the set of objects that when added to 2^2 yield 5, respectively:

$$\{x \mid x + 4 = 5\}$$

$$\{x \mid x + 2^2 = 5\}$$

In what follows, we sometimes render Frege's notation in this more modern notation.

Frege took advantage of his second-order language to *define* what it is for an object to be a member of an extension. Although Frege used the notation $x \frown y$ to designate the membership relation, we shall follow the more usual practice of using $x \in y$. Thus, the following captures the main features of Frege's definition of membership in **Gg I**, §34:

$x \in y =_{df} \exists G(y = \acute{\varepsilon} G\varepsilon \ \& \ Gx)$

In other words, *x* is an element of *y* just in case *x* falls under a concept of which *y* is the extension. For example, given this definition, one can prove that John is a member of the extension of the concept *being happy* (formally: $j \in \acute{\varepsilon} H\varepsilon$) from the premise that John falls under the concept *being happy* ('*Hj*'). Here is a simple proof:

1. Hj	Premise
2. $\acute{\varepsilon} H\varepsilon = \acute{\varepsilon} H\varepsilon$	= Introduction
3. $\acute{\varepsilon} H\varepsilon = \acute{\varepsilon} H\varepsilon \ \& \ Hj$	from 1,2, by & Introduction
4. $\exists G(\acute{\varepsilon} H\varepsilon = \acute{\varepsilon} G\varepsilon \ \& \ Gj)$	from 3, by Existential Introduction
5. $j \in \acute{\varepsilon} H\varepsilon$	from 4, by definition of $\in$

Some readers may wish to examine a somewhat more complex example, in which the above definition of membership is used to prove that $1 \in \acute{\alpha}(\alpha + 2^2 = 5)$ given the premise that $1 + 2^2 = 5$. (A More Complex Example)

Basic Law V

Frege attempted to axiomatize courses-of-values and extensions by formulating Basic Law V. The reader should now be in a position to see how the following formulation of Basic Law V corresponds to Frege's formulation in **Gg I**, §20:

Basic Law V:
$\acute{\varepsilon} f(\varepsilon) = \acute{\alpha} g(\alpha) \equiv \forall x[f(x) = g(x)]$

This principle asserts: the course-of-values of the function *f* is identical to the course-of-values of the function *g* if and only if *f* and *g* map every object to the same value. [Actually, Frege uses an identity sign instead of the biconditional sign as the main connective of the principle. The reason he could do this is that, in his system, when two sentences are materially equivalent, they *name* the same truth value.]

Basic Law V has the following special case, when the functions *f* and *g* are the concepts *F* and *G*:

Basic Law V (Special Case):
$\acute{\varepsilon} F\varepsilon = \acute{\alpha} G\alpha \equiv \forall x(Fx \equiv Gx)$

[Here, again, Frege used an identity sign in place of the biconditional signs.] In this special case, Basic

Law V asserts: the extension of the concept *F* is identical to the extension of the concept *G* if and only if all and only the objects that fall under *F* fall under *G* (i.e., if and only if the concepts *F* and *G* are materially equivalent). In more modern guise, Frege's Basic Law V asserts that the set of *F*s is identical to the set of *G*s if and only if *F* and *G* are materially equivalent:

$$\{x|Fx\} = \{y|Gy\} \equiv \forall z(Fz \equiv Gz)$$

The second example discussed in the subsection Notation for Courses of Values can now be seen as an instance of Basic Law V:

$$\grave{\varepsilon}(\varepsilon + 4 = 5) = \grave{\alpha}(\alpha + 2^2 = 5) \equiv \forall x(x + 4 = 5 \equiv x + 2^2 = 5)$$

This simply asserts that the extension of the concept *that which added to* 4 *yields* 5 is identical to the extension of the concept *that which added to* 2^2 *yields* 5 if and only if all and only the objects that when added to 4 yield 5 are objects that when added to 2^2 yield 5.

Basic Law V looks like it asserts a very general truth. In fact, it does correctly imply the Law of Extensions and the Principle of Extensionality. The Law of Extensions (cf. **Gg I**, §55, Theorem 1) asserts that an object is a member of the extension of a concept if and only if it falls under that concept:

Law of Extensions:
$\forall F \forall x(x \in \grave{\varepsilon}F\varepsilon \equiv Fx)$

(Proof of the Law of Extensions)

Basic Law V also correctly implies the Principle of Extensionality. This principle asserts that if two extensions have the same members, they are identical. If we let the expression '*Extension*(*x*)' abbreviate the formula '$\exists F(x = \grave{\varepsilon}F\varepsilon)$' then we may formally represent and derive the principle of extensionality as follows:

Principle of Extensionality:
$Extension(x)\ \&\ Extension(y) \rightarrow [\forall z(z \in x \equiv z \in y) \rightarrow x = y]$

(Proof of the Principle of Extensionality)

Despite these deceptive successes of Basic Law V, the fact is that it can't be consistently added to Frege's system. In the following subsections, we shall show how Basic Law V proves to be inconsistent with the rest of Frege's second order logic and theory of concepts. The proofs depend essentially on the second order character of Frege's system and on the second-order definition of the membership relation. Frege was made aware of the inconsistency by Bertrand Russell, who sent him a letter formulating 'Russell's Paradox' just as the second volume of **Gg** was going to press. Frege quickly added an Appendix to the

second volume, describing two distinct ways of deriving a contradiction from Basic Law V. The first establishes the contradiction directly, without any special definitions. The second deploys the membership relation and more closely follows Russell's Paradox. We will examine both derivations of the contradiction in what follows.

Both derivations of the contradiction turn on an important corollary to Basic Law V, namely, that every concept has an extension:

> **Corollary to Basic Law V**:
> $\forall F \exists x(x = \acute{\alpha} F\alpha)$

To see that this is a consequence of Basic Law V, note that when we instantiate the variable *G* to *F* in Basic Law V, we can establish:

$$\acute{\varepsilon} F\varepsilon = \acute{\alpha} F\alpha \equiv \forall x(Fx \equiv Fx)$$

Since the right side of this instance of Law V can be derived by logic alone, it follows that $\acute{\varepsilon} F\varepsilon = \acute{\alpha} F\alpha$. But, then, by existential generalization, it follows that:

$$\exists x(x = \acute{\alpha} F\alpha)$$

But now our *Corollary* follows by universal generalization on the concept variable *F*. However, the combination of Frege's Rule of Substitution (which ensures that there is a concept corresponding to every formula with free variable *x*) and Basic Law V (which ensures that each concept has an extension that behaves in a certain way), turns out to be a volatile mix.

First Derivation of the Contradiction

In the Appendix to **Gg II**, Frege shows that a contradiction can be derived once we formulate the concept *being the extension of a concept which you don't fall under*. The following open formula expresses this concept:

$$\exists F(x = \acute{\alpha} F\alpha \ \& \ \neg Fx)$$

From the Comprehension Principle for Concepts (or Frege's Rule of Substitution), we know that there exists a concept corresponding to this formula and we may use the following λ-expression to name it:

$$[\lambda x \ \exists F(x = \acute{\alpha} F\alpha \ \& \ \neg Fx)]$$

Now by the *Corollary* to Basic Law V and our Rewrite Rule, the extension of this concept exists and can

be designated as follows:

$$\acute{\varepsilon}[\exists F(\varepsilon = \acute{\alpha}F\alpha \ \& \ \neg F\varepsilon)]$$

It can now be proved that this extension falls under the concept $[\lambda x\, \exists F(x = \acute{\alpha}F\alpha \ \& \ \neg Fx)]$ if and only if it does not. (First Derivation of the Contradiction.)

Second Derivation of the Contradiction

Frege next (in the Appendix to **Gg II**) explained how Basic Law V implies the Naive Comprehension Axiom for extensions or sets, which Russell's Paradox shows to be inconsistent. From the Law of Extensions (which was derived from Basic Law V above), one can establish the Naive Comprehension Axiom for extensions in three simple steps. First we instantiate the Law of Extensions to the free variable *F*, to yield:

$$\forall x(x \in \acute{\varepsilon}F\varepsilon \equiv Fx)$$

Then by generalizing on the extension $\acute{\varepsilon}F\varepsilon$, it follows that:

$$\exists y \forall x(x \in y \equiv Fx)$$

Now at this point, we may universally generalize on the variable *F* to get the following second-order Naive Comprehension Axiom for extensions, which asserts that for every concept *F*, there is an extension which has as members all and only the objects that fall under *F*:

Naive Comprehension Axiom for Extensions:
$\forall F \exists y \forall x(x \in y \equiv Fx)$

Alternatively, instead of generalizing, we could have appealed to Frege's Rule of Substitution to show that all of the instances of the following Naive Comprehension Schema for extensions are derivable in Frege's system:

Naive Comprehension Schema for Extensions:
$\exists y \forall x(x \in y \equiv \varphi(x))$, where $\varphi(x)$ is any formula in which x is free and which contains no free occurrences of y

This asserts that for any formula $\varphi(x)$ defining a condition on objects, there is an extension which has as members all and only the objects that meet the condition.

Both the Naive Comprehension Axiom and the Naive Comprehension Schema immediately give rise to

Russell's Paradox in the context of Frege's logic. In the case of the axiom, the contradiction follows by instantiating the quantified variable F to the concept $[\lambda z\, \neg(z \in z)]$. In the case of the schema, the contradiction follows by taking $\varphi(x)$ to be $\neg(x \in x)$, as follows:

$$\exists y \forall x(x \in y \equiv \neg(x \in x))$$

In either case, the proof of the contradiction goes through. The derivation of the contradiction from the above instance of the schema is particularly easy. For suppose the object b is such a y. Then:

$$\forall x(x \in b \equiv \neg(x \in x))$$

But we can now instantiate the universal claim to the object b to yield the following contradiction:

$$b \in b \equiv \neg(b \in b)$$

(See the entry on Russell's Paradox.)

How the Paradox is Engendered

Philosophers have diagnosed the inconsistency in Frege's system in various ways, and it is safe to say that the matter is still somewhat controversial. In this subsection, we discuss only the basic elements of the problem. Most philosophers and logicians agree that the reason Frege's second-order logic and theory of extensions is inconsistent is that they jointly require the impossible situation in which the domain of concepts has to be strictly larger than the domain of extensions while at the same time the domain of extensions has to be as large as the domain of concepts. This impossible situation is strikingly analogous to the impossible situation set up in the proof by *reductio* of Cantor's Theorem (Cantor's Theorem asserts that if A is any set, and B is the power set of A (i.e., B is the set of all subsets of A), then B has more members than A; the proof by reductio shows that it is impossible for there to be a function from A *onto* B).

To analyze the inconsistency in Frege's system in more detail, it is important to discuss the conditions under which concepts are to be identified. Although Frege did not believe that statements of the form '$F = G$' were meaningful, it is evident from the study of **Gg** that the material equivalence of concepts F and G serves as the proxy identity conditions of F and G. So, whenever it is *not* the case that all and only the objects that fall under F fall under G, F and G are distinct concepts.

With this in mind, we can see how the paradox is engendered. Recall first that the *Corollary* to Basic Law V reveals that Basic Law V correlates each concept with an extension. Each direction of Basic Law V requires that this correlation have certain properties. We shall see, for example, that the right-to-left direction of Basic Law V (i.e., Va) requires that no concept gets correlated with two distinct extensions. [Frege uses the label 'Va' to designate the right-to-left direction of Basic Law V. See, for example, **Gg I**, §52. However, many commentators use 'Va' to designate the left-to-right direction. We shall follow

Frege's use, since that will make sense of his Appendix to **Gg II**, in which he discusses the paradoxes.] Va asserts:

> **Basic Law Va**:
> $\forall x(Fx \equiv Gx) \rightarrow \acute{\varepsilon}F\varepsilon = \acute{\alpha}G\alpha$

If we think in terms of its contraposition and remember the identity conditions for concepts, Va in effect asserts that whenever extensions differ, the concepts with which they are correlated differ. This means that the correlation between concepts and extensions that Basic Law V sets up must be a function---no concept gets correlated with two distinct extensions (though for all Va tells us, distinct concepts might get correlated with the same extension). Frege noted (in the Appendix to **Gg II**) that this direction of Basic Law V doesn't seem problematic.

However, the left-to-right direction of Basic Law V (i.e., Vb) is more serious. Vb asserts:

> **Basic Law Vb**:
> $\acute{\varepsilon}F\varepsilon = \acute{\alpha}G\alpha \rightarrow \forall x(Fx \equiv Gx)$

If we consider the contrapositive of this and remember the identity conditions for concepts, then Vb, in effect, asserts that whenever the concepts *F* and *G* differ, the extensions of *F* and *G* differ. So, the correlation that Basic Law V sets up between concepts and extensions will have to be one-to-one; i.e., it correlates distinct concepts with distinct extensions. Since every concept is correlated with some extension, there have to be at least as many extensions as there are concepts.

But the problem is that Frege's system *as a whole* requires that there be *more* concepts than extensions. The requirement that there be more concepts than extensions is imposed jointly by the Comprehension Principle for Concepts *and* the new significance this principle takes on in the presence of Basic Law V. The Comprehension Principle for Concepts asserts the existence of a concept for every condition on objects expressible in the language. Now though it may seem that this forces the domain of concepts to be larger than the domain of objects, it is a model-theoretic fact that there are models of second-order logic with the Comprehension Principle for Concepts (but without Basic Law V) in which the domain of concepts need not be larger than the domain of objects.[1] However, the Comprehension Principle for Concepts takes on new significance when Basic Law V is added to Frege's system. The synergism of the Comprehension Principle for Concepts and Basic Law V force the domain of concepts to be larger than the domain of objects (and so larger than the domain of extensions). However, as we saw in the last paragraph, Vb requires that there be at least as many extensions as there are concepts.

Thus, Frege's second-order logic and theory of extensions together required the impossible situation in which the domain of concepts has to be strictly larger than the domain of extensions while at the same time the domain of extensions has to be as large as the domain of concepts.

Recently, there has been a lot of interest in discovering ways of repairing Frege's system. The traditional

view is that one must either restrict Basic Law V or restrict the Comprehension Principle for Concepts. Recently, Boolos (1986, 1993) developed one of the more interesting suggestions for revising Basic Law V without abandoning second-order logic and its comprehension principle for concepts. On the other hand, there have been many suggestions for restricting the Comprehension Principle for Concepts. The most severe of these is to abandon second-order logic (and the Comprehension Principle for Concepts) altogether. Schroeder-Heister (1987) conjectured that the first-order portion of Frege's system (i.e., the system which results by adding Basic Law V to the first-order predicate calculus) was consistent and this was proved by Parsons (1987) and Burgess (1998).[2] Heck (1996) and Wehmeier (1999) consider less drastic moves. They investigate systems of second-order logic which have been extended by Basic Law V but in which the Comprehension Principle for Concepts is restricted in some way. We will not discuss their investigations further in the present entry, for it is not clear which of their alternatives, or others, would have been acceptable to Frege. Instead, we focus on the theoretical accomplishment revealed by Frege's work in **Gg**.

Despite the failure of Basic Law V, Frege validly proved a rather deep fact about the natural numbers, namely, that the Dedekind/Peano axioms for number theory could be derived in second-order logic with the help of a single additional principle. The principle in question is known as Hume's Principle (discussed below). Although both Parsons (1965) and Wright (1983) had recently noted that Hume's Principle was powerful enough for the derivation of the Dedekind/Peano axioms, Heck (1993) showed that although Frege did use Basic Law V to derive Hume's principle, his (Frege's) subsequent derivations of the Dedekind/Peano axioms of number theory from Hume's Principle never made an *essential* appeal to Basic Law V. Since Hume's Principle just by itself is consistent with second-order logic, this means that Frege validly derived the basic laws of number theory. It will be the task of the next few sections to explain Frege's accomplishments in this regard. We will do this in two stages. In §3 we study Frege's attempt to derive Hume's Principle from Basic Law V by analyzing cardinal numbers as extensions. Then, we put this aside in §§4 and 5 to examine how Frege was able to derive the Dedekind/Peano axioms of number theory from Hume's Principle alone.

§3: Frege's Analysis of Cardinal Numbers

Cardinal numbers are the numbers that can be used to answer the question ‘How many?’, and Frege discovered that such numbers bear an interesting relationship to the natural numbers. Frege's insights concerning this relationship trace back to his work in **Gl**, in which the notion of an extension played very little role. The seminal idea of **Gl**, §46, was the observation that a statement of number (e.g., "There are nine planets") is an assertion about a concept. To explain this idea, Frege noted that one and the same external phenomenon can be counted in different ways; for example, a certain external phenomenon could be counted as one army, 5 divisions, 25 regiments, 120 companies, 400 platoons, or 4000 people. Each different way of counting this phenomenon corresponds to the manner of its conception. The question "How many are there?" is only properly formulated as the question "How many *F*s are there?" where a concept *F* is supplied. On Frege's view, the statements of number which answer such questions (e.g., "There are *n* *F*s") tell us something about the concept involved. For example, the statement "There are nine planets in the solar system" tells us that the ordinary, *first-level* concept *planet in the solar system*

falls under the *second-level* numerical concept *concept under which nine objects fall*.

Frege then moves from this realization, in which statements of numbers are analyzed as predicating second-level numerical concepts of first-level concepts, to develop an account of the cardinal and natural numbers as ‘self-subsistent’ objects. He introduces a ‘cardinality operator’ on concepts, namely, ‘the number belonging to the concept *F*’, which will designate the cardinal number which numbers the objects falling under *F*. In what follows, we say this more simply as ‘the number of *F*s’ and use the simple notation ‘#F’. Frege offers both an implicit and an explicit definition of this operator in **Gl**. Both of these definitions require a preliminary definition of when two concepts *F* and *G* are in one-to-one correspondence or ‘equinumerous’. After developing the definition of equinumerosity, we then discuss Frege's implicit and explicit definition of the number of *F*s.

Equinumerosity

In order to state the definition of equinumerosity, we shall employ the well-known logical notion ‘there exists a unique x such that $\varphi(x)$’. To say that there exists a unique x such that $\varphi(x)$ is to say: there is some x such that $\varphi(x)$ and anything y which is such that $\varphi(y/x)$ is identical to x. In what follows, we use the notation ‘$\exists!x\varphi(x)$’ to abbreviate this notion of unique existence, and we define it formally as follows:

$$\exists!x\varphi(x) \quad =_{df} \quad \exists x[\varphi(x) \;\&\; \forall y(\varphi(y/x) \rightarrow y{=}x)]$$

Now, in terms of this logical notion of unique existence, we can state Frege's definition of equinumerosity (**Gl**, §71, 72) as follows:

> *F* and *G* are *equinumerous* (or, *F* and *G* are in *one-to-one correspondence*) just in case there is a relation *R* such that: (1) every object falling under *F* is *R*-related to a unique object falling under *G*, and (2) every object falling under *G* is such that there is a unique object falling under *F* which is *R*-related to it.

If we let ‘$F \approx G$’ stand for equinumerosity, then the definition of this notion can be rendered formally as follows:

$$F \approx G \quad =_{df}$$
$$\exists R[\forall x(Fx \rightarrow \exists!y(Gy \;\&\; Rxy)) \quad \& \quad \forall x(Gx \rightarrow \exists!y(Fy \;\&\; Ryx))]$$

To see that Frege's definition of equinumerosity works correctly, consider the following two examples. In the first example, we have two concepts that are equinumerous:

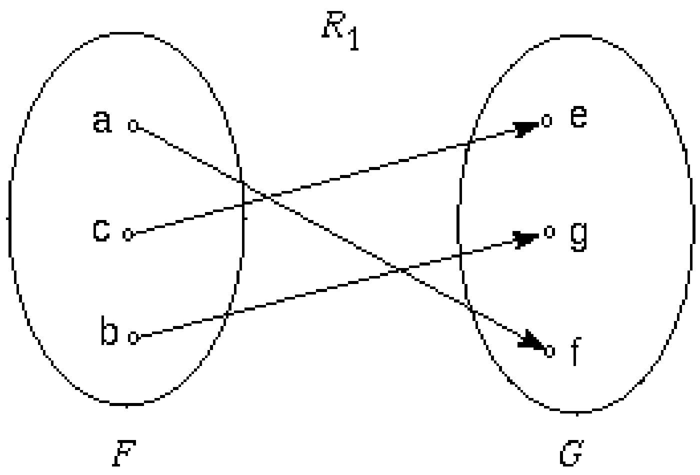


Figure 1

Although there are several different relations *R* which would demonstrate the equinumerosity of *F* and *G* the particular relation used in Figure 1 is:

$$R_1 = [\lambda xy\ (x{=}a\ \&\ y{=}f) \vee (x{=}b\ \&\ y{=}g) \vee (x{=}c\ \&\ y{=}e)]$$

It is a simple exercise to show that R_1, as defined, is a ‘witness’ to the equinumerosity of *F* and *G* (according to the definition).

In the second example, we have two concepts that are not equinumerous:

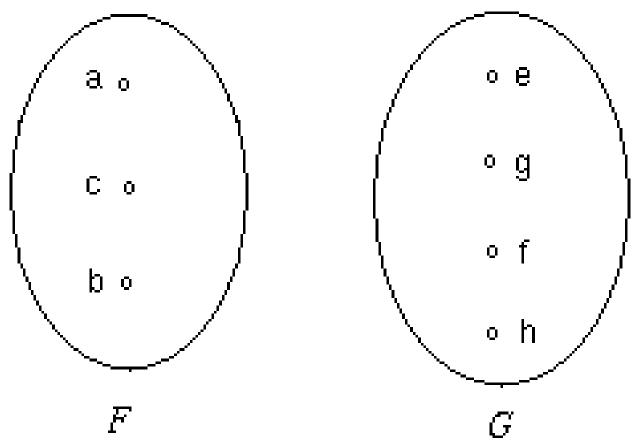

Figure 2

In this example, no relation *R* can satisfy the definition of equinumerosity.

Clearly, then, the concepts *F* and *G* will be equinumerous whenever the number of objects falling under *F* is identical to the number of objects falling under *G*. This fact will be codified by Hume's Principle. Before moving ahead to the discussion of this principle, the reader should convince him- or herself of the following four facts: (1) that the material equivalence of two concepts implies their equinumerosity, (2) that equinumerosity is reflexive, (3) that equinumerosity is symmetric, and (4) that equinumerosity is

transitive. In formal terms, the following facts are provable:

> **Facts About Equinumerosity**:
> 1. $\forall x(Fx \equiv Gx) \rightarrow F \approx G$
> 2. $F \approx F$
> 3. $F \approx G \rightarrow G \approx F$
> 4. $F \approx G \;\&\; G \approx H \rightarrow F \approx H$

The proofs of these facts, in each case, require the identification of a relation that is a witness to the relevant equinumerosity claim. In some cases, it is easy to identify the relation in question. In other cases, the reader should be able to ‘construct’ such relations (using λ-notation) by considering the examples described above. Facts (2) - (4) establish that equinumerosity is an ‘equivalence relation’ which divides up the domain of concepts into ‘equivalence classes’ of equinumerous concepts. Material equivalence is also an equivalence relation which divides up the domain of concepts into equivalence classes of materially equivalent concepts.

Contextual Definition of ‘The Number of *F*s’: Hume's Principle

Frege contextually defined ‘the number of *F*s’ in terms of the principle now known as Hume's Principle:[3]

> **Hume's Principle**:
> The number of *F*s is identical to the number of *G*s if and only if *F* and *G* are equinumerous.

Using our notation ‘#*F*’ to abbreviate ‘the number of *F*s’, we may formalize Hume's Principle as follows:

> **Hume's Principle**:
> $\#F = \#G \;\equiv\; F \approx G$

This contextual definition governing cardinal numbers is the basic principle upon which Frege forged his development of the theory of natural numbers.[4] In **Gl**, Frege sketched the derivations of the basic laws of number theory from Hume's Principle; these sketches were developed into more rigorous proofs in **Gg I**. We will examine these derivations in the following sections.

Once Frege had a contextual definition of #*F*, he then defined a cardinal number as any object which is the number of some concept:

> *x is a cardinal number* $=_{df}$ $\exists F(x = \#F)$

This definition appears in **Gl**, §72.

Notice that Hume's Principle bears an obvious formal resemblance to Basic Law V. Both are biconditionals asserting the equivalence of an identity among singular terms (the left-side condition) with an equivalence relation on concepts (the right-side condition). Indeed, both correlate concepts with certain objects. In the case of Hume's Principle, each concept F is correlated with $\#F$. However, whereas Basic Law V problematically asserts that the correlation between concepts and extensions is one-to-one, Hume's Principle only asserts that the correlation between concepts and numbers is many-to-one. Hume's Principle often correlates distinct concepts with the same number. For example, the distinct concepts *author of Principia Mathematica* (‘$[\lambda x\, Axp]$’) and *number between* 1 *and* 4 (‘$[\lambda x\, 1 < x < 4]$’) are equinumerous (both both have two objects falling under them). So $\#[\lambda x\, Axp] = \#[\lambda x\, 1 < x < 4]$. Thus, Hume's Principle, unlike Basic Law V, does not require that the domain of numbers be as large as the domain of concepts. Indeed, Hume's Principle has recently been proved consistent with second-order logic. This was shown independently by Burgess (1984) and Hazen (1985).

Explicit Definition of ‘The Number of *F*s’

[Note: The remaining two subsections are not strictly necessary for understanding the proof of Frege's Theorem. They are included here for those who wish to have a more complete understanding of what Frege in fact attempted to do. They presuppose the material in §2. Readers interested in just the positive aspects of Frege's accomplishments should skip directly to §4.]

Before we examine the powerful consequences that Frege derived from Hume's Principle, it is worth digressing to describe his failed attempt to explicitly define ‘$\#F$’ and to derive Hume's Principle from Basic Law V. The idea behind this attempt was the realization that if given any concept F, the notion of equinumerosity can be used to define the second-level concept *being a concept G that is equinumerous to F* (‘$G \approx F$’). Frege found a way to collect all of the concepts equinumerous to a given concept F into a single extension. In **Gl**, he informally took this to be an extension consisting of first-order concepts. In that work, he defined informally (§68):

> the number of Fs $=_{df}$
> the extension of the second-level concept: *being a first-level concept equinumerous to F*

In terms of the example used at the end of the previous subsection, this definition identifies the number of the concept *author of Principia Mathematica* as the extension consisting of all and only those first-level concepts that are equinumerous to this concept; this extension has both $[\lambda x\, Axp]$ and $[\lambda x\, 1 < x < 4]$ as members. Frege in fact identifies the cardinal number 2 with this extension, for it contains all and only those concepts under which two objects fall. Similarly, Frege identifies the cardinal number 0 with the extension consisting of all those first-level concepts under which no object falls; this extension would include such concepts as *unicorn*, *centaur*, *prime number between* 3 *and* 5, etc. Frege's insight here inspired Russell to develop a somewhat similar definition in his work, and it is now common to see references to the so-called "Frege-Russell definition of the cardinal numbers" as classes of equinumerous concepts or sets.[5] Of course, this explicit definition of ‘the number of *F*s’ stands or falls with a coherent

conception of ‘extension’. We know that Basic Law V does not offer such a coherent conception.

Derivation of Hume's Principle

Frege's derivation of Hume's Principle was invalidated by the fact that it appeals to the inconsistent Basic Law V. Nevertheless, it is instructive to consider why Frege thought the derivation was valid. In **Gl**, §73, Frege sketches an informal proof of the right-to-left direction of Hume's Principle using the above explicit definition of the number of *F*s. The derivation appeals to the fact that a concept *G* is a member of the extension of the second-level concept *concept equinumerous to F* if and only if *G* is equinumerous to *F*. In other words, the proof relies on a kind of higher-order version of the Law of Extensions (described above), the ordinary version of which we know to be a consequence of Basic Law V.[6] Here is a reconstruction of Frege's proof in **Gl**, §73, extended so as to cover both directions of Hume's Principle.

> Frege's Derivation of Hume's Principle in **Gl**

However, in the development of **Gg**, Fregean extensions do *not* contain concepts as members but rather objects. So Frege had to find another way to express the explicit definition described in the previous subsection. His technique was to let extensions go proxy for their corresponding concepts. Since a full explanation of this technique and the proof of Hume's Principle in **Gg** would constitute a digression for the present exposition, we shall describe the details for interested readers on a separate page:

> Frege's `Derivation' of Hume's Principle in **Gg**

As noted on several occasions, the inconsistency in Basic Law V invalidated Frege's derivation of Hume's Principle. But Hume's Principle, in and of itself, is a powerful and consistent principle.

§4: Frege's Analysis of Predecessor, Ancestrals, and the Natural Numbers

In what follows, we shall suppose that Hume's Principle has replaced Basic Law V in Frege's second-order system. This requires that we replace the operator "the course of values of the function *f*" (and "the extension of concept *F*") with the primitive operator "the number of Fs". As we have mentioned, Frege made the insightful discovery that the basic laws of number theory could be derived from Hume's Principle alone. This is Frege's Theorem. In this section, we introduce the definitions required for the proof of Frege's Theorem. In the next section, we go through the proof. In the final section, we conclude with a discussion of the philosophical questions that arise when we consider Hume's Principle as a replacement for Basic Law V.

The insight behind Frege's analysis of the natural numbers was the realization that one can define the finite cardinal numbers in terms of the following concepts:

$C_0 = [\lambda x \;\; x \neq x]$
$C_1 = [\lambda x \;\; x = \#C_0]$
$C_2 = [\lambda x \;\; x = \#C_0 \;\; \vee \;\; x = \#C_1]$
$C_3 = [\lambda x \;\; x = \#C_0 \;\; \vee \;\; x = \#C_1 \;\; \vee \;\; x = \#C_2]$
etc.

Note that starting with C_1, each concept C_k has the following property: all and only the numbers of concepts preceding C_k in the sequence fall under C_k. So, for example, the concepts preceding C_3 are C_0, C_1, and C_2. Accordingly, all and only the following numbers fall under C_3: $\#C_0$, $\#C_1$, and $\#C_2$.

Frege noticed that these concepts can be used, respectively, to define the the finite cardinal numbers, as follows:

$0 = \#C_0$
$1 = \#C_1$
$2 = \#C_2$
etc.

This insight, however, was only the first step in Frege's plan. He realized that though this seems to define a sequence of numbers with which we can identify the natural numbers, we have not as yet defined the concept ‘natural number’ so that it applies to all and only the cardinal numbers defined in the second sequence. Such a concept is required if we are to prove *as theorems* the following axioms of Dedekind/Peano number theory:

Dedekind/Peano Axioms for Number Theory:

- 0 is a natural number.
- 0 is not the successor of any natural number.
- No two natural numbers have the same successor.
- If both (a) 0 falls under *F*, and (b) for any two natural numbers *n* and *m*, the fact that *n* falls under *F* implies that *m* falls under *F*, then every natural number falls under *F*. (Principle of Induction)
- Every natural number has a successor.

Moreover, Frege recognized the need to employ the Principle of Induction in the proof that every number has a successor. One cannot prove the claim that *every number has a successor* simply by producing the sequence of expressions for cardinal numbers (e.g., the second of the two sequences described above). All such a sequence demonstrates is that for every expression listed in the sequence, one can define an expression of the appropriate form to follow it in the sequence. This is *not* the same as proving that *every natural number* has a successor.

Predecessor

To accomplish these further goals, Frege proceeded by defining the concept *x* (*immediately*) *precedes y* as follows (**Gl**, §76, and **Gg I**, §43):

> *x* (*immediately*) *precedes y* if and only if there is a concept *F* and an object *w* such that: (a) *w* falls under *F*, (b) *y* is the number of *F*s, and (c) *x* is the number of the concept *object falling under F other than w*

In formal terms, the definition takes the following form:

$$Precedes(x,y) \ =_{df}$$
$$\exists F \exists w(Fw \ \ \& \ \ y = \#F \ \ \& \ \ x = \#[\lambda z\, Fz \,\&\, z \neq w])$$

Even though we can't as yet assume that we have defined the natural numbers 1 and 2, we can use them intuitively to show that the definition properly predicts that *Precedes*(1,2) if given certain facts about the numbers of certain concepts. Let the expression '[λ*z Azp*]' denote the concept *author of Principia Mathematica*. Only Bertrand Russell ('*r*') and Alfred Whitehead fall under this concept. Let the expression '[λ*z Azp* & *z*≠*r*]' denote the concept *author of Principia Mathematica other than Russell*.[7] Then the following may, for the purposes of this example, be taken as facts:

- Russell falls under the concept *author of Principia Mathematica*, i.e.,
  $[\lambda z\, Azp]r$
- 2 is the number of the concept *author of Principia Mathematica*, i.e.,
  $2 = \#[\lambda z\, Azp]$
- 1 is the number of the concept *author of Principia Mathematica other than Russell*, i.e.,
  $1 = \#[\lambda z\, Azp \,\&\, z \neq r]$

If we assemble these truths into a conjunction and apply existential generalization in the appropriate places, the result is the definiens of the definition of predecessor instantiated to the numbers 1 and 2. Thus, if given certain facts about the number of objects falling under the certain concepts, the definition of predecessor correctly predicts that *Precedes*(1,2).

The Ancestral of Relation *R*

Frege next defines the relational concept *x is an ancestor of y in the R-series*. This new relation is called 'the ancestral of the relation *R*' and we henceforth designate this relation as *R**. Frege first defined the ancestral of relation *R* in **Begr** (Part III, Proposition 76), though the word 'ancestral' comes to us from Russell and Whitehead. Frege's term for the ancestral is "*x* comes before *y* in the *R*-series"; alternatively, "*y* follows *x* in the *R*-series". (See also **Gl**, §79 and **Gg I**, §45.) The intuitive idea is easily grasped if we

consider the relation *x* is the father of *y*. Suppose that *a* is the father of *b*, that *b* is the father of *c*, and that *c* is the father of *d*. Then '*x* is an ancestor of *y* in the fatherhood-series' is defined so that *a* is an ancestor of *b*, *c*, and *d*, that *b* is an ancestor of *c* and *d*, and that *c* is an ancestor of *d*.

Frege's definition of the ancestral of *R* requires a preliminary definition:

> *the concept F is hereditary in the R-series* if and only if any pair of *R*-related objects *x* and *y* are such that *y* falls under *F* whenever *x* falls under *F*

In formal terms:

$$Her(F,R) =_{abbr} \forall x \forall y(Rxy \mathbin{\&} \mathrm{F}x \rightarrow \mathrm{F}y)$$

Intuitively, the idea is that *F* is hereditary in the *R*-series if *F* is always 'passed' from *x* to *y* whenever *x* and *y* are a pair of *R*-related objects. (We warn the reader here that the notation '*Her*(*F*,*R*)' is merely an abbreviation of a much longer statement. It is *not* a formula of our language having the form '*R*(*x*,*y*)'. In what follows, we sometimes introduce other such abbreviations.)

Frege's definition of the ancestral of *R* can now be stated as follows:

> *x comes before y in the R-series* $=_{df}$ *y* falls under all those *R*-hereditary concepts *F* under which falls every object to which *x* is *R*-related

In other words, *y* follows *x* in the *R*-series whenever *y* falls under every hereditary concept *F* which *x* 'passes on' to all of its immediate descendants. In formal terms:

$$R^*(x,y) =_{df} \forall F[\forall z(Rxz \rightarrow Fz) \mathbin{\&} Her(F,R) \rightarrow Fy]$$

For example, Clinton's father stands in relation *father* of* (i.e., *forefather*) to Chelsea because she falls under every hereditary concept that Clinton and his brother inherited from Clinton's father. However, Clinton's brother is not one of Chelsea's forefathers, since he fails to be her father, her grandfather, or any of the other links in the chain of fathers from which Chelsea descended.

It is important to grasp the differences between a relation *R* and its ancestral *R**. *Rxy* implies *R**(*x*,*y*) (e.g., if Clinton is a father of Chelsea, then Clinton is a forefather of Chelsea), but the converse doesn't hold (Clinton's father is a father* of Chelsea, but he is not a father of Chelsea). Indeed, a grasp of the definition of *R** should leave one able to prove the following easy consequences, many of which correspond to theorems in **Begr** and **Gg**:[8]

Facts About *R**:

1. $Rxy \rightarrow R^*(x,y)$
2. $\neg(R^*(x,y) \rightarrow Rxy)$
3. $\exists x R^*(x,y) \rightarrow \exists x\, Rxy$
4. $Rxy \;\&\; R^*(y,z) \rightarrow R^*(x,z)$
5. $[R^*(x,y) \;\&\; \forall z(Rxz \rightarrow Fz) \;\&\; Her(F,R)] \rightarrow Fy$
6. $[Fx \;\&\; R^*(x,y) \;\&\; Her(F,R)] \rightarrow Fy$
7. $R^*(x,y) \;\&\; R^*(y,z) \rightarrow R^*(x,z)$

The reader should consider what happens when *R* is taken to be the relation *precedes*. Appealing to our intuitive grasp of the numbers, we can say that it is an instance of Fact (1) that if 10 precedes 12, then 10 precedes* 12; and that it is an instance of Fact (2) that 10's preceding* 12 does not imply that 10 precedes 12. An instance of Fact (7) is that precedes* is transitive. When we restrict ourselves to the natural numbers, it is intuitive to think of the difference between precedes and precedes* as the difference between *immediately precedes* and *less-than*.

The Weak Ancestral of *R*

Given the notion of the ancestral of relation *R*, Frege then defines its weak ancestral, which he termed "*y is a member of the R-series beginning with x*" (cf. **Begr**, Part III, Proposition 99; **Gl**, §81, and **Gg I**, §46):

> *y is a member of the R-series beginning with x* if and only if either *x* bears the ancestral of *R* to *y* or *x* = *y*

In formal terms:

$$R^+(x,y) \;=_{df}\; R^*(x,y) \vee x=y$$

We note here that Frege would also read $R^+(x,y)$ as: *x* is a member of the *R*-series ending with *y*! Logicians call R^+ the ‘weak-ancestral’ of *R* because it is a weakened version of R^*. When *R* is *precedes*, we can intuitively regard its weak ancestral, *precedes*$^+$, as the relation *less-than-or-equal-to* on the natural numbers.

The general definition of the weak ancestral of *R* yields the following facts, many of which correspond to theorems in **Gg**:[9]

Facts About R^+:

1. $Rxy \rightarrow R^+(x,y)$
2. $R^+(x,y) \;\&\; Ryz \rightarrow R^*(x,z)$
3. $R(x,y) \;\&\; R^+(y,z) \rightarrow R^*(x,z)$
4. $R^*(x,y) \;\&\; Ryz \rightarrow R^+(x,z)$

5. $R^*(x,y) \rightarrow \exists z[Rzy \,\&\, R^+(x,z)]$ (Proof of Fact 5 Concerning the Weak Ancestral)
6. $[Fx \,\&\, R^+(x,y) \,\&\, Her(F,R)] \rightarrow Fy$
7. $R^*(x,y) \,\&\, Rzy \,\&\, R$ is 1-1 $\rightarrow R^+(x,z)$[10]
8. $R^+(x,x)$ (Reflexivity)

The proofs of these facts are left as exercises.

The Concept *Natural Number*

Frege's definition of *natural number* requires one more preliminary definition. It may be recalled that that Frege identified the number 0 as the (cardinal) number of the concept *being non-self-identical*. That is:

$$0 =_{df} \#[\lambda x\, x \neq x]$$

Since the logic of identity guarantees that no object fails to be self-identical, nothing falls under the concept *being non-self-identical*. Had one of Frege's explicit definitions of the cardinal numbers worked as he had intended, the number 0 would, in effect, be identified with the extension of all (extensions of) concepts under which nothing falls. However, for the present purposes, we may note that 0 is defined in terms of the primitive notion ‘the number of *F*s’ and a particular complex concept the existence of which is guaranteed in Frege's theory of concepts and second-order logic with identity. It is straightforward to prove the following Lemma Concerning Zero from this definition of 0:

> **Lemma Concerning Zero**:
> $\#F = 0 \equiv \neg\exists x Fx$
>
> (Proof of Lemma Concerning Zero)

Note that the proof appeals to Hume's Principle and facts about equinumerosity.

Frege's definition of the concept *natural number* can now be stated in terms of the weak-ancestral of Predecessor:

> *x is a natural number* if and only if *x* is a member of the predecessor-series beginning with 0

This definition appears in **Gl**, §83, and **Gg I**, §46 as the definition of ‘finite number’. Indeed, the natural numbers are precisely the finite cardinals. In formal terms, Frege's definition becomes:

$$\mathbb{N}x =_{df} Precedes^+(0,x)$$

In what follows, we shall sometimes use the variables *m*, *n*, and *o* to range over the natural numbers.

§5: Frege's Theorem

Frege's Theorem is that the five Dedekind/Peano axioms for number theory can be derived from Hume's Principle in second-order logic. In this section, we reconstruct the proof of this theorem which can be extracted from Frege's work using the definitions and theorems assembled so far. Some of the steps in this proof can be found in **Gl**. (See the Appendix to Boolos (1990) for a reconstruction.) Our reconstruction follows Frege's **Gg** in spirit and in most details, but we have tried to simplify the presentation in several places. For a more strict description of Frege's **Gg** proof, the reader is referred to Heck (1993). The following should help prepare the reader for Heck's excellent essay.

Zero is a Number

The following is an immediate consequence of the definition of *natural number*:

> **Theorem 1**:
> $\mathbb{N}0$
>
> *Proof*: It is a simple consequence of the definition of 'weak ancestral' that R^+ is reflexive (see Fact 8 about R^+ in our subsection on the Weak Ancestral in §4). So $Precedes^+(0,0)$. Hence, by the definition of number, 0 is a number.

It seems that Frege never actually identified this fact explicitly in **Gl** or labeled this fact as a numbered Theorem in **Gg I**. It is possible that he thought it was too obvious to mention.

Zero Isn't the Successor of Any Number

It is also a simple consequence of the foregoing that 0 doesn't succeed any number. This can be represented formally as follows:

> **Theorem 2**:
> $\neg\exists x(\mathbb{N}x \;\&\; Precedes(x,0))$
>
> *Proof*: Assume, for *reductio*, that some object, say *b*, does precede 0. Then, by the definition of predecessor, it follows that there is a concept, say *Q* and an object falling under *Q*, say *c*, such that 0 is #*Q*. But this contradicts the Lemma Concerning Zero (above). Since nothing precedes 0, no natural number precedes 0.

See **Gl**, §78, Item (6); and **Gg I**, §109, Theorem 126.

No Two Numbers Have the Same Successor

The fact that no two numbers have the same successor is somewhat more difficult to prove (cf. **Gl**, §78, Item (5); **Gg I**, §95, Theorem 89). We may formulate this theorem as follows, with m, n, and o as restricted variables ranging over the natural numbers:

> **Theorem 3**:
> $\forall m \forall n \forall o[Precedes(m,o)\ \&\ Precedes(n,o) \rightarrow m = n]$

In other words, this theorem asserts that predecessor is a one-to-one relation on the natural numbers. To prove this theorem, it suffices to prove that predecessor is a one-to-one relation full stop. One can prove that predecessor is one-to-one from Hume's Principle, with the help of the following Equinumerosity Lemma, the proof of which is rather long and involved. The Equinumerosity Lemma asserts that when *F* and *G* are equinumerous, *x* falls under *F*, and *y* falls under *G*, then the concept *object falling under F other than x* is equinumerous to the concept *object falling under G other than y*. The picture is something like this:

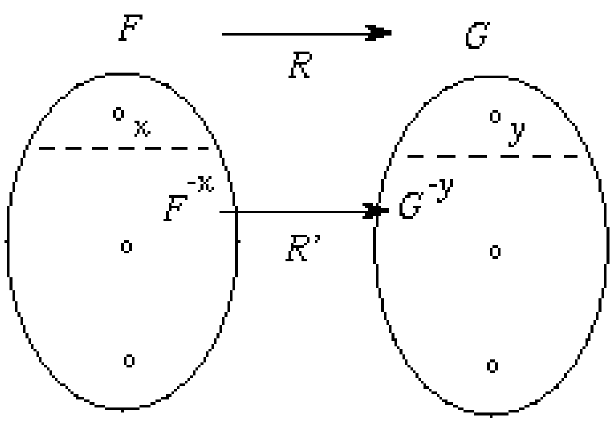

Figure 3

In terms of Figure 3, the Equinumerosity Lemma tells us that if there is a relation *R* which is a witness to the equinumerosity of *F* and *G*, then there is a relation R' which is a witness to the equinumerosity of the concepts that result when you restrict *F* and *G* to the objects other than *x* and *y*, respectively.

To help us formalize the Equinumerosity Lemma, let F^{-x} abbreviate the concept $[\lambda z\ Fz\ \&\ z \neq x]$ and let G^{-y} abbreviate the concept $[\lambda z\ Gz\ \&\ z \neq y]$. Then we have:

> **Equinumerosity Lemma**:
> $F \approx G\ \&\ Fx\ \&\ Gy \rightarrow F^{-x} \approx G^{-y}$

(Proof of Equinumerosity Lemma)

Now we can prove that Predecessor is a one-to-one relation from this Lemma and Hume's Principle (cf. **Gg I**, §108):

> **Predecessor is One-to-One**:
> $\forall x \forall y \forall z[Precedes(x,z) \,\&\, Precedes(y,z) \rightarrow x = y]$
>
> *Proof*: Assume that both *a* and *b* are precedessors of *c*. By the definition of predecessor, we know that there are concepts and objects *P*, *Q*, *d*, and *e*, such that:
>
> - $Pd \;\&\; c = \#P \;\&\; a = \#P^{-d}$
> - $Qe \;\&\; c = \#Q \;\&\; b = \#Q^{-e}$
>
> But if both $c = \#P$ and $c = \#Q$, then $\#P = \#Q$. So, by Hume's Principle, $P \approx Q$. So, by the Equinumerosity Lemma, it follows that $P^{-d} \approx Q^{-e}$. If so, then by Hume's Principle, $\#P^{-d} = \#Q^{-e}$. But then, $a = b$.

So, if Predecessor is a one-to-one relation, it is a one-to-one relation on the natural numbers. Therefore, no two numbers have the same successor.

It is important to mention here that not only is Predecessor a one-to-one relation, it is also a function:

> **Predecessor is a Function**:
> $\forall x \forall y \forall z[Precedes(x,y) \,\&\, Precedes(x,z) \rightarrow y = z]$

This fact can be proved with the help of a kind of converse to the Equinumerosity Lemma:

> **Equinumerosity Lemma 'Converse'**:
> $F^{-x} \approx G^{-y} \;\&\; Fx \;\&\; Gy \;\rightarrow\; F \approx G$

We leave the proof of the Equinumerosity Lemma 'Converse' and the proof that Predecessor is a function as exercises for the reader. The fact that Predecessor is a function will play a part in the proof that every number has a successor.

The Principle of Mathematical Induction

Let us say that a concept *F* is *hereditary on the natural numbers* just in case every 'adjacent' pair of numbers *n* and *m* (*n* preceding *m*) is such that *m* falls under *F* whenever *n* falls under *F*, i.e.,

> $HerOn(F,\mathbb{N}) \;=_{abbr}\; \forall n \forall m[Precedes(n,m) \rightarrow (Fn \rightarrow Fm)]$

Then we may state the Principle of Mathematical Induction as follows: if (a) 0 falls under *F* and (b) *F* is

hereditary on the natural numbers, then every natural number falls under *F*. In formal terms:

> **Principle of Mathematical Induction**:
> $F0 \;\&\; HerOn(F,\mathbb{N}) \rightarrow \forall n\, Fn$

Frege actually proves the Principle of Mathematical Induction from a more general principle that governs any *R*-series whatsoever. We will call the latter the General Principle of Induction. It asserts that whenever *a* falls under *F*, and *F* is hereditary on the *R*-series beginning with *a*, then every member of that *R*-series falls under *F*. We can formalize the General Principle of Induction with the help of a more strict understanding of 'hereditary on the *R*-series beginning with *a*'. Here is a definition:

$$HerOn(F, {}^{a}R^{+}) =_{abbr} \forall x \forall y[R^{+}(a,x) \;\&\; R^{+}(a,y) \;\&\; Rxy \;\rightarrow\; (Fx \rightarrow Fy)]$$

In other words, *F* is hereditary on the members of the *R*-series beginning with *a* just in case every adjacent pair *x* and *y* in this series (with *x* bearing *R* to *y*) is such that *y* falls under *F* whenever *x* falls under *F*. Now given this definition, we can reformulate the General Principle of Induction more strictly as:

> **General Principle of Induction**:
> $[Fa \;\&\; HerOn(F, {}^{a}R^{+})] \rightarrow \forall x[R^{+}(a,x) \rightarrow Fx]$

This is a version of Frege's Theorem 152 in **Gg I**, §117.

Frege's proves this claim by making an insightful appeal to his Rule of Substitution. We may sketch the proof strategy as follows. Assume that the antecedent of the General Principle of Induction holds for an arbitrarily chosen concept, say *P*. That is, assume:

$$Pa \;\;\&\;\; HerOn(P, {}^{a}R^{+})$$

Now to show $\forall x(R^{+}(a,x) \rightarrow Fx)$, pick an arbitrary object, say *b*, and further assume $R^{+}(a,b)$. We then simply have to show *Pb*. Frege does this by using the Rule of Substitution on Fact (6) about R^{+} (in our subsection on the Weak Ancestral in §4). Recall that Fact (6) is:

$$[Fx \;\&\; R^{+}(x,y) \;\&\; Her(F,R)] \rightarrow Fy$$

This is a theorem of logic containing the free variables *x*, *y*, and *F*. Frege instantiates *x* and *y* to *a* and *b*, respectively. He then, as we might put it, instantiates *F* to the concept $[\lambda z\, R^{+}(a,z) \;\&\; Pz]$ and applies λ-Conversion. (This is where Frege used his Rule of Substitution.) The concept being instantiated for *F* is the concept *member of the R-series beginning with a and which falls under P*. The result of instantiating all the free variables in Fact (6) and then applying λ-Conversion yields a rather long conditional, with numerous conjuncts in the antecedent and the claim that *Pb* in the consequent. Thus, if the antecedent can

be established, the proof is done. However, for those following along with pencil and paper, all of the conjuncts to this conditional are things we already know, with the exception of the claim that [λz R^+(*a*,*z*) & *Pz*] is hereditary on *R*. However, this claim can be established straightforwardly from things we know to be true (and, in particular, from facts contained in the antecedent of the Principle we are trying to prove, which we assumed as part of our conditional proof). The reader is encouraged to complete the proof as an exercise. For those who would like to check their work, we give the complete Proof of the General Principle of Induction here. (Proof of the General Principle of Induction)

Now to derive Principle of Mathematical Induction from the General Principle of Induction, we formulate the instance of the latter in which *a* is 0 and *R* is *Precedes*:

$$[F0 \ \& \ HerOn(F, {}^{0}Precedes^{+})] \ \rightarrow \ \forall x[Precedes^{+}(0,x) \rightarrow Fx]$$

When we expand the defined notation for *HerOn*, substitute the notation ℕ*x* and ℕ*y* for $Precedes^+(0,x)$ and $Precedes^+(0,y)$, respectively, and then employ our restricted quantifiers ∀*n*(...*n*...) and ∀*m*(...*m*...) for the claims of the form ∀*y*(ℕ*y* → ...*y*...) and ∀*x*(ℕ*x* → ...*x*...), respectively, the result is the Principle of Mathematical Induction (in which the notation *HerOn*(*F*,ℕ) has been eliminated in terms of its definiens).

Every Number Has a Successor

Frege uses the Principle of Mathematical Induction to prove that every number has a successor in the natural numbers. We may formulate the theorem as follows:

> **Theorem 5**:
> $\forall x[\mathbb{N}x \rightarrow \exists y(\mathbb{N}y \ \& \ Precedes(x,y))]$

To understand Frege's strategy for proving this theorem, recall that the weak ancestral of the Predecessor relation, i.e., $Precedes^+(x,y)$, can be read as: *x* is a member of the predecessor-series ending with *y*. Frege then considers the concept *member of the predecessor-series ending with n*, i.e., [λz $Precedes^+(z,n)$], where *n* is a natural number. Frege then shows, by induction, that every natural number *n* precedes the number of the concept *member of the predecessor-series ending with n*. That is, Frege proves that every number has a successor by proving the following Lemma on Successors by induction:

> **Lemma on Successors**:
> $\forall n \ Precedes(n, \#[\lambda z \ Precedes^{+}(z,n)])$

This asserts that every number *n* precedes the number of numbers in the predecessor series ending with *n*. Frege can establish Theorem 5 by proving the Lemma on Successors and by showing that the successor of a natural number is itself a natural number.

To see an intuitive picture of why the Lemma on Successors gives us what we want, we may temporarily

regard Precedes$^+$ as the relation $\leq$. (One can prove that Precedes$^+$ has the properties that $\leq$ has on the natural numbers.) Although we haven't yet defined the natural numbers following 0, the following intuitive sequence is driving Frege's strategy:

> 0 precedes $\#[\lambda z\, z \leq 0]$
> 1 precedes $\#[\lambda z\, z \leq 1]$
> 2 precedes $\#[\lambda z\, z \leq 2]$
> etc.

For example, the third member of this sequence is true because there are 3 natural numbers (0, 1, and 2) that are less than or equal to 2; so the number 2 precedes the number of numbers less than or equal to 2. Frege's strategy is to show that the general claim, that *n* precedes the number of numbers less than or equal to *n*, holds for every natural number. So, given this intuitive understanding of the Lemma on Successors, Frege has a good strategy for proving that every number has a successor. (For the remainder of this subsection, the reader may wish to continue to think of Precedes$^+$ in terms of $\leq$.)

Now to prove the Lemma on Successors by induction, we need to reconfigure this Lemma to a form which can be used as the consequent of the Principle of Induction; i.e., we need something of the form $\forall n\, Fn$. We can get the Lemma on Successors into this form by 'abstracting out' a concept from the Lemma using the right-to-left direction of λ-Conversion to produce the following equivalent statement of the Lemma:

$$\forall n\, [\lambda y\, Precedes(y, \#[\lambda z\, Precedes^+(z,y)])]n$$

The concept 'abstracted out' is the following:

$$[\lambda y\, Precedes(y, \#[\lambda z\, Precedes^+(z,y)])]$$

This is the concept: *being an object y which precedes the number of the concept: member of the predecessor series ending in y*. Let us abbreviate the λ-expression that denotes this concept as '*Q*'. Then Frege's strategy is to instantiate the variable *F* in the Principle of Induction (using his Rule of Substitution) to *Q*. The result is therefore something that we may take as having been proved:

$$Q0\ \&\ HerOn(Q,\mathbb{N}) \rightarrow \forall n\, Qn$$

Since the consequent is the Lemma on Successors, Frege can prove this Lemma by proving both that 0 falls under *Q* (cf. **Gg I**, Theorem 154) and that *Q* is hereditary on the natural numbers (cf. **Gg I**, Theorem 150):

> Proof that 0 falls under *Q*

Proof that *Q* is hereditary on the natural numbers

Given this proof of the Lemma on Successors, Theorem 5 is not far away. The Lemma on Successors shows that every number precedes some cardinal number of the form *#F*. We still have to show that such successor cardinals are natural numbers. That is, it still remains to be shown that if a number *n* precedes something *y*, then *y* is a natural number:

Successors of Natural Numbers are Natural Numbers:
$\forall n \forall y(Precedes(n,y) \rightarrow \mathbb{N}y)$

Proof: Suppose that *Precedes*(*n*,*a*). Then, by definition, since *n* is a natural number, $Precedes^{+}(0,n)$. So by Fact (2) about R^{+} (in the subsection on the Weak Ancestral in §4), it follows that $Precedes^{*}(0,a)$, and so by the definition of $Precedes^{+}$, it follows that $Precedes^{+}(0,a)$; i.e., *a* is a natural number.

Theorem 5 now follows from the Lemma on Successors and the fact that successors of natural numbers are natural numbers. With the proof of Theorem 5, we have completed the proof of Frege's Theorem. Before we turn to the last section of this entry, it is worth mentioning the mathematical significance of this theorem.

Arithmetic
